Abstract

We consider quivers/skew-symmetric matrices under the action of mutation (in the cluster algebra sense). We classify those which are isomorphic to their own mutation via a cycle permuting all the vertices, and give families of quivers which have higher periodicity.

The periodicity means that sequences given by recurrence relations arise in a natural way from the associated cluster algebras. We present a number of interesting new families of non-linear recurrences, necessarily with the Laurent property, of both the real line and the plane, containing integrable maps as special cases. In particular, we show that some of these recurrences can be linearised and, with certain initial conditions, give integer sequences which contain all solutions of some particular Pell equations. We extend our construction to include recurrences with *parameters*, giving an explanation of some observations made by Gale.

Finally, we point out a connection between quivers which arise in our classification and those arising in the context of quiver gauge theories.

Keywords: cluster algebra, quiver mutation, Somos sequence, integer sequences, Pell's equation, Laurent phenomenon, integrable map, linearisation, Seiberg duality, supersymmetric quiver gauge theory.

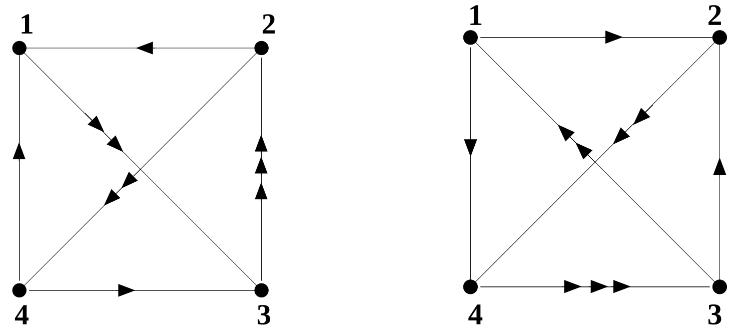
1 Introduction

Our main motivation for this work is the connection between cluster algebras and integer sequences which are Laurent polynomials in their initial terms [7]. A key example of this is the Somos 4 sequence, which is given by the following recurrence:

$$x_n x_{n+4} = x_{n+1} x_{n+3} + x_{n+2}^2. \tag{1}$$

This formula (with appropriate relabelling of the variables) coincides with the cluster exchange relation associated with the vertex 1 in the quiver S_4 of Figure 1(a). Mutation of S_4 at 1 gives the quiver shown in Figure 1(b) and transforms the cluster (x_1, x_2, x_3, x_4) into $(\tilde{x}_1, x_2, x_3, x_4)$, where $\tilde{x}_1$ is given by

$$x_1 \tilde{x}_1 = x_2 x_4 + x_3^2.$$



(a) The Somos 4 quiver, S_4. (b) Mutation of S_4 at 1.

Figure 1: The Somos 4 quiver and its mutation at 1.

Remarkably, after this *complicated operation* of mutation on the quiver the result is a simple rotation, corresponding to the relabelling of indices $(1, 2, 3, 4) \mapsto (4, 1, 2, 3)$. Therefore, a mutation of the new quiver at 2 gives the *same formula* for the exchange relation (up to a relabelling). It is this simple property that allows us to think of an infinite sequence of such mutations as the simple **iteration** (1).

In this paper, we classify quivers with this property. In this way we obtain a classification of maps which could be said to be 'of Somos type'. In fact we consider a more general type of "mutation periodicity", which corresponds to Somos type sequences of higher dimensional spaces.

It is interesting to note that many of the quivers which have occurred in the theoretical physics literature concerning *supersymmetric quiver gauge theories* are particular examples from our classification; see for example [4, §4]. We speculate that some of our other examples may be of interest in that context.

We now describe the contents of the article in more detail. In Section 2, we recall matrix and quiver mutation from [6], and introduce the notion of periodicity we are considering. It turns out to be easier to classify periodic quivers if we assume that certain vertices are sinks; we call such quivers *sink-type*. In Section 3, we classify the sink-type quivers of period 1 as nonnegative integer combinations of a family of *primitive* quivers. In Section 4, we do the same for sink-type period 2 quivers, and in Section 5 we classify the sink-type quivers of arbitrary period.

In Section 6, we give a complete classification of all period 1 quivers (without the sink assumption), and give some examples. It turns out the arbitrary period 1 quivers can be described in terms of the primitives with n nodes, together with the primitives for quivers with k nodes for all k less than n of the same parity (Theorem 6.6).

In Section 7, we classify quivers of period 2 with at most 5 nodes. These descriptions indicate that a full classification for higher period is likely to be significantly more complex than the classification of period 1 quivers. However, it is possible to construct a large family of period 2 (not of sink-type) quivers, which we present in Section 7.4.

In Section 8, we describe the recurrences that can be associated to period 1 and period 2 quivers via Fomin-Zelevinsky cluster mutation. The nature of the cluster exchange relation means that the recurrences we have associated to periodic quivers are in general nonlinear. However, in Section 9, we show that the recurrences associated to period 1 primitives can be linearised. This allows us to conclude in Section 9 that certain simple linear combinations of subsequences of the first primitive period 1 quiver (for arbitrarily many nodes) provide all the solutions to an associated Pell equation.

In Section 10 we extend our construction of mutation periodic quivers to include quivers with *frozen* cluster variables, thus enabling the introduction of *parameters* into the corresponding recurrences. As a result, we give an explanation of some observations made by Gale in [10].

In Section 11, we give an indication of the connections with supersymmetric quiver gauge theories.

In Section 12, we present our final conclusions. Section 13 is an appendix to Section 9.

2 The Periodicity Property

We consider quivers with no 1 cycles or 2-cycles (i.e. the quivers on which cluster mutation is defined). Any 1- or 2-cycles which arise through operations on the quiver will be cancelled. The vertices of Q will be assumed to lie on the vertices of a regular n-sided polygon, labelled $1, 2, \ldots, n$ in clockwise order.

In the usual way, we shall identify a quiver Q, with n nodes, with the unique skew-symmetric $n \times n$ matrix B_Q with $(B_Q)_{ij}$ given by the number of arrows from i to j minus the number of arrows from j to i.. We next recall the definition of quiver mutation [6].

Definition 2.1 (Quiver Mutation) *Given a quiver Q we can mutate at any of its nodes. The mutation of Q at node k, denoted by $\mu_k Q$, is constructed (from Q) as follows:*

1. *Reverse all arrows which either originate or terminate at node k.*
2. *Suppose that there are p arrows from node i to node k and q arrows from node k to node j (in Q). Add pq arrows going from node i to node j to any arrows already there.*
3. *Remove (both arrows of) any two-cycles created in the previous steps.*

Note that Step 3 is independent of any choices made in the removal of the two-cycles, since the arrows are not labelled. We also note that in Step 2, pq is just the number of paths of length 2 between nodes i and j which pass through node k.

Remark 2.2 (Matrix Mutation) *Let B and $\tilde{B}$ be the skew-symmetric matrices corresponding to the quivers Q and $\tilde{Q} = \mu_k Q$. Let b_{ij} and $\tilde{b}_{ij}$ be the corresponding matrix entries. Then quiver mutation amounts to the following formula*

$$\tilde{b}_{ij} = \begin{cases} -b_{ij} & \text{if } i = k \text{ or } j = k, \\ b_{ij} + \frac{1}{2}(|b_{ik}| b_{kj} + b_{ik} |b_{kj}|) & \text{otherwise.} \end{cases} \tag{2}$$

This is the original formula appearing (in a more general context) in [6]. We consider a sequence of mutations, starting at node 1, followed by node 2, and so on. Mutation at node 1 of a quiver $Q(1)$ will produce a second quiver $Q(2)$. The mutation at node 2 will therefore be of quiver $Q(2)$, giving rise to quiver $Q(3)$ and so on. If, after m steps, $Q(m+1)$ is *equivalent* (up to a permutation of the nodes) to $Q(1)$, we say that $Q(1)$ is a period m quiver. If m is minimal, we say that it is strictly of period m. In fact, it follows that each of the quivers $Q(1), \cdots, Q(m)$ is of period m. In this paper we only consider cyclic permutations of order n (for an n node quiver).

We number the nodes from 1 to n (clockwise ascending) and consider the permutation $\rho : (1, 2, \cdots, n) \to (n, 1, \cdots, n-1)$, represented by the matrix

$$\rho = \begin{pmatrix} 0 & \cdots & \cdots & 1 \\ 1 & 0 & & \vdots \\ & \ddots & \ddots & \vdots \\ & & 1 & 0 \end{pmatrix}.$$

Such a permutation acts on a quiver Q in such a way that the number of arrows from i to j in Q is the same as the number of arrows from $\rho^{-1}(i)$ to $\rho^{-1}(j)$ in $\rho(Q)$. Thus the arrows of Q are rotated clockwise while the nodes remain fixed (alternatively, this operation can be interpreted as leaving the arrows fixed whilst the nodes are moved in an anticlockwise direction). We will always fix the positions of the nodes in our diagrams.

Definition 2.3 *We will say that a quiver Q has period m if it satisfies $Q(m+1) = \rho^m Q(1)$, with the mutation sequence depicted by*

$$Q = Q(1) \xrightarrow{\mu_1} Q(2) \xrightarrow{\mu_2} \cdots \xrightarrow{\mu_{m-1}} Q(m) \xrightarrow{\mu_m} Q(m+1) = \rho^m Q(1). \tag{3}$$

We call the the above sequence of quivers the periodic chain *associated to Q.*

Remark 2.4 (Admissible sequences) *Recall that an* admissible sequence *of sinks in an acyclic quiver Q is a total ordering $v_1, v_2, \ldots, v_n$ of its vertices such that v_1 is a sink in Q and v_i is a sink in $\mu_{v_{i-1}}\mu_{v_{i-2}}\cdots\mu_{v_1}(Q)$ for $i = 2, 3, \ldots, n$. Such a sequence always has the property that $\mu_{v_n}\mu_{v_{n-1}}\cdots\mu_{v_1}(Q) = Q$ [1, §5.1]. This notion is of importance in the representation theory of quivers.*

We note that if any (not necessarily acyclic) quiver Q has period 1 in our sense, then $\mu_1 Q = \rho Q$. It follows that $\mu_n\mu_{n-1}\cdots\mu_1 Q = Q$. Thus any period 1 quiver has a property which can be regarded as a generalisation of the notion of existence of an admissible sequence of sinks. In fact, higher period quivers also possess this property (since, as we shall see, the period must divide the number of vertices).

3 Period 1 Quivers

We now introduce a finite set of particularly simple quivers of period 1, which we shall call the *period* 1 *primitives*. Remarkably, it will later be seen that in a certain sense they form a "basis" for the set of all quivers of period 1. We shall also later see that period m primitives can be defined as certain sub-quivers of the period 1 primitives.

Recall that a node i of a quiver Q is said to be a *sink* if all arrows incident with i end at i, and is said to be a *source* if all arrows incident with i start at i.

Definition 3.1 (Period 1 sink-type quivers) *A quiver Q is said to be a* period 1 sink-type quiver *if it is of period 1 and node 1 of Q is a sink.*

Definition 3.2 (Skew-rotation) *We shall refer to the matrix*

$$\tau = \begin{pmatrix} 0 & \cdots & \cdots & -1 \\ 1 & 0 & & \vdots \\ & \ddots & \ddots & \vdots \\ & & 1 & 0 \end{pmatrix}.$$

as a skew-rotation*.*

Lemma 3.3 (Period 1 sink-type equation) *A quiver Q with a sink at 1 is period 1 if and only if $\tau B_Q \tau^{-1} = B_Q$.*

Proof: If node 1 of Q is a sink, there are no paths of length 2 through it, and the second part of Definition 2.1 is void. Reversal of the arrows at node 1 can be done through a simple conjugation of the matrix B_Q:

$$\mu_1 B_Q = \delta_1 B_Q \delta_1, \quad \text{where} \quad \delta_1 = \mathrm{diag}(-1, 1, \cdots, 1).$$

Equating this to $\rho B_Q \rho^{-1}$ leads the equation $\tau B_Q \tau^{-1} = B_Q$ as required, noting that

$$\tau = \delta_1 \rho.$$

□

Since $\tau^n = -I_n$, the action (on square matrices) $M \mapsto \tau M \tau^{-1}$ is of order n. This gives us a method for building period 1 matrices: we sum over τ-orbits.

The period 1 primitives $P_n^{(k)}$. We consider a quiver with just a single arrow from $n-k+1$ to 1, represented by the skew-symmetric matrix $R_n^{(k)}$ with $(R_n^{(k)})_{n-k+1,1} = 1$, $(R_n^{(k)})_{1,n-k+1} = -1$ and $(R_n^{(k)})_{ij} = 0$ otherwise.

We define skew-symmetric matrices $B_n^{(k)}$ as follows:

$$B_n^{(k)} = \begin{cases} \sum_{i=0}^{n-1} \tau^i R_n^{(k)} \tau^{-i}, & \text{if } n = 2r+1 \text{ and } 1 \le k \le r, \text{ or if } n = 2r \text{ and } 1 \le k \le r-1; \\ \sum_{i=0}^{r-1} \tau^i R_n^{(r)} \tau^{-i}, & \text{if } k = r \text{ and } n = 2r. \end{cases} \tag{4}$$

Let $P_n^{(k)}$ denote the quiver corresponding to $B_n^{(k)}$. We remark that the geometric action of τ in the above sum is to rotate the arrow clockwise without change of orientation, except that when the tail of the arrow ends up at node 1 it is reversed. It follows that 1 is a sink in the resulting quiver. Since it is a sum over a τ-orbit, we have $\tau B_n^{(k)} \tau^{-1} = B_n^{(k)}$, and thus that $P_n^{(k)}$ is a period 1 sink-type quiver. In fact, we have the simple description:

$$B_n^{(k)} = \begin{cases} \tau^k - (\tau^t)^k, & \text{if } n = 2r+1 \text{ and } 1 \le k \le r, \text{ or } n = 2r \text{ and } 1 \le k \le r-1; \\ \tau^r, & \text{if } n = 2r \text{ and } k = r. \end{cases}$$

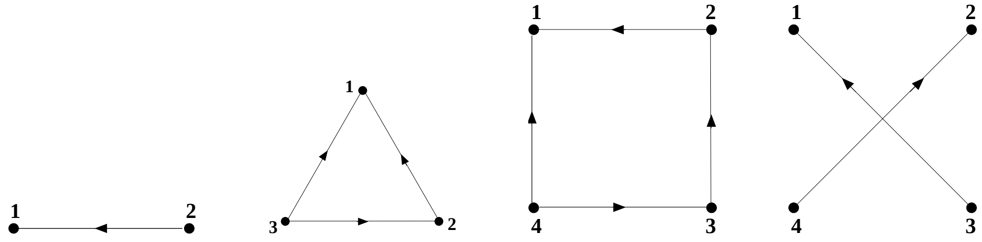
where τ^t denotes the transpose of τ.

Note that we have restricted to the choice $1 \le k \le r$ because when $k > r$, our construction gives nothing new. Firstly, consider the case $n \neq 2k$. Then $B_n^{(n+1-k)} = B_n^{(k)}$, because the primitive $B_n^{(k)}$ has exactly two arrows ending at 1: those starting at $k+1$ and at $n+k-1$. Starting with either of these arrows produces the same result. If $n = 2k$, these two arrows are identical, and since τ itself is skew-symmetric, $\tau^k - (\tau^t)^k = 2\tau^k$. The sum over $n = 2k$ terms just goes twice over the sum over r terms.

In this construction we could equally well have chosen node 1 to be a source. We would then have $R_n^{(k)} \mapsto -R_n^{(k)}$, $B_n^{(k)} \mapsto -B_n^{(k)}$ and $P_n^{(k)} \mapsto (P_n^{(k)})^{opp}$, where Q^{opp} denotes the opposite quiver of Q (with all arrows reversed). Our original motivation in terms of sequences with the Laurent property is derived through cluster exchange relations, which do not distinguish between a quiver and its opposite, so we consider these as equivalent.

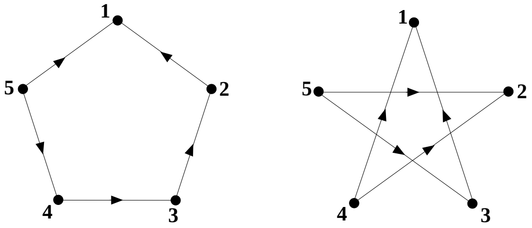
Remark 3.4 *We note that each primitive is a disjoint union of cycles or arrows, i.e. quivers whose underlying graph is a union of components which are either of type A_2 or of type $\widetilde{A}_m$ for some m.*

Figures 2 to 4 show the period 1 primitives we have constructed, for $2 \le n \le 6$.



(a) $P_2^{(1)}$ (b) $P_3^{(1)}$ (c) $P_4^{(1)}$ (d) $P_4^{(2)}$

Figure 2: The period 1 primitives for 2, 3 and 4 nodes.



(a) $P_5^{(1)}$ (b) $P_5^{(2)}$

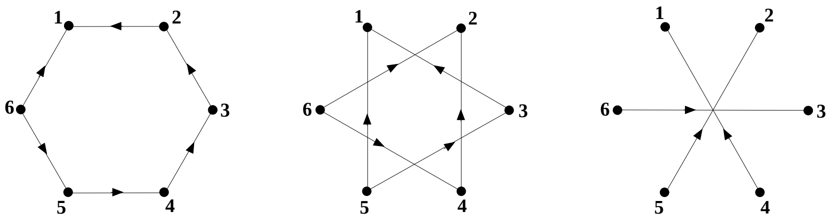
Figure 3: The period 1 primitives for 5 nodes.

Remark 3.5 (An Involution $\iota : Q \mapsto Q^{opp}$) *It is easily seen that the following permutation of the nodes is a symmetry of the primitives $P_n^{(i)}$ (if we consider Q and Q^{opp} as equivalent):*

$$\iota : (1, 2, \cdots, n) \mapsto (n, n-1, \cdots, 1).$$

In matrix language, this follows from the facts that $\iota R_n^{(k)} \iota = -R_n^{(k)}$ and $\iota \tau \iota = \tau^t$, where $\iota = \begin{pmatrix} 0 & & 1 \\ & \iddots & \\ 1 & & 0 \end{pmatrix}$.

It is interesting to note that ρ is a Coxeter element in Σ_n regarded as a Coxeter group, while ι is the longest element.



(a) $P_6^{(1)}$ (b) $P_6^{(2)}$ (c) $P_6^{(3)}$

Figure 4: The period 1 primitives for 6 nodes.

We may combine primitives to form more complicated quivers. Consider the sum

$$P = \sum_{i=1}^{r} m_i P_n^{(i)},$$

where $n = 2r$ or $2r + 1$ for r an integer and the m_i are arbitrary integers. It is easy to see that the corresponding quiver is a period 1 sink-type quiver whenever $m_i \geq 0$ for all i. In fact, we have:

Proposition 3.6 (Classification of period 1 sink-type quivers) *Let $n = 2r$ or $2r + 1$, where r is an integer. Every period 1 sink-type quiver with n nodes has corresponding matrix of the form $B = \sum_{k=1}^{r} m_k B_n^{(k)}$, where the m_k are arbitrary nonnegative integers.*

Proof: Let B be the matrix of a period 1 sink-type quiver. It remains to show that B is of the form stated. We note that τ permutes the set of summands appearing the definition (4) of the $B_n^{(k)}$, i.e. the elements $\tau^i R_n^{(k)} \tau^{-i}$ for $0 \leq i \leq n-1$ and $1 \leq k \leq r$ if $n = 2r+1$, for $0 \leq i \leq n-1$ and $1 \leq k \leq r-1$ if $n = 2r$, together with the elements $\tau^i R_n^{(r)} \tau^{-i}$ for $0 \leq i \leq r-1$ if $n = 2r$. These $\frac{1}{2}n(n-1)$ elements are easily seen to form a basis of the space of real skew-symmetric matrices. By Lemma 3.3, $\tau B \tau^{-1} = B$, so B is a linear combination of the period 1-primitives (which are the orbit sums for the conjugation action of τ on the above basis), necessarily an integer combination since B is an integer matrix. Since B is sink-type, all the m_k must be nonnegative.$\square$

Note that this means all period 1 sink-type quivers are invariant under ι in the above sense. We also note that if the m_k are taken to be of mixed sign, then Q is no longer periodic without the addition of further “correction” terms. Theorem 6.6 gives these correction terms.

4 Period 2 Quivers

Period 2 primitives will be defined in a similar way. First, we make the following definition:

Definition 4.1 (Period 2 sink-type quivers) *A quiver Q is said to be a* period 2 sink-type quiver *if it is of period 2, node 1 of $Q(1) = Q$ is a sink, and node 2 of $Q(2) = \mu_1 Q$ is a sink.*

Let Q be a period 2 quiver. Then we have two quivers in our periodic chain (3), $Q(1)$ and $Q(2) = \mu_1(Q)$, with corresponding matrices $B(1), B(2)$. If $Q(1)$ is of sink-type then, since node 1 is a sink in $Q(1)$, the mutation $Q(1) \mapsto \mu_1 Q(1) = Q(2)$ again only involves the reversal of arrows at node 1. Similarly, since node 2 is a sink for $Q(2)$, the mutation $Q(2) \mapsto \mu_2 Q(2)$ only involves the reversal of arrows at node 2.

Obviously each period 1 quiver Q is also period 2, where $B(2) = \rho B(1) \rho^{-1}$. However, we will construct some strictly period 2 primitives.

As before, we have:

Lemma 4.2 (Period 2 sink-type equation) *Suppose that Q is a quiver with a sink at 1 and that $Q(2)$ has a sink at 2. Then Q is period 2 if and only if $\tau^2 B_Q \tau^{-2} = B_Q$.*

Proof: As before, reversal of the arrows at node 1 of Q can be achieved through a simple conjugation of its matrix: $\mu_1 B_Q = \delta_1 B_Q \delta_1$. Similarly, reversal of the arrows at node 2 of $Q(2)$ can be achieved through

$$\mu_2 B_Q(2) = \delta_2 B_Q(2) \delta_2, \quad \text{where} \quad \delta_2 = \mathrm{diag}(1, -1, 1, \cdots, 1) = \rho \delta_1 \rho^{-1}.$$

Equating the composition to $\rho^2 B_Q \rho^{-2}$ leads to the equation

$$B_Q = \delta_1\delta_2\rho^2 B_Q \rho^{-2}\delta_2\delta_1 = \tau^2 B_Q \tau^{-2}.$$

□

Following the same procedure as for period 1, we need to form orbit-sums for τ^2 on the basis considered in the previous section; we shall call these period 2 primitives.

A τ-orbit of odd cardinality is also a τ^2-orbit, so the orbit sum will be a period 2 primitive which is also of period 1. Thus we cannot hope to get period 2 solutions which are not also period 1 solutions unless there are an even number of nodes. A τ-orbit of even cardinality splits into two τ^2-orbits.

When $n = 2r$, the matrices $R_n^{(k)}$, for $1 \le k \le r-1$, generate strictly period 2 primitives $P_{n,2}^{(k,1)}$, with matrices given by

$$B_{n,2}^{(k,1)} = \sum_{i=0}^{r-1} \tau^{2i} R_n^{(k)} \tau^{-2i},$$

If, in addition, n is divisible by 4, we obtain the additional strictly period 2 primitives $P_{n,2}^{(r,1)}$, with matrices given by:

$$B_{n,2}^{(r,1)} = \sum_{i=0}^{r/2-1} \tau^{2i} R_n^{(r)} \tau^{-2i}.$$

Geometrically, the primitive $P_{n,2}^{(k,1)}$ is obtained from the period 1 primitive $P_n^{(k)}$ by "removing half the arrows" (the ones corresponding to odd powers of τ). The removed arrows form another period 2 primitive, called $P_{n,2}^{(k,2)}$, which may be defined as the matrix:

$$B_{n,2}^{(k,2)} = \tau B_{n,2}^{(k,1)} \tau^{-1}.$$

The matrix $B_{n,2}^{(k,2)}$ can be related to $\mu_1 B_{n,2}^{(k,1)} = B_{n,2}^{(k,1)}(2)$ as follows. For $1 \le k \le r-1$, we have

$$\begin{aligned}
\rho^{-1}\mu_1 B_{n,2}^{(k,1)}\rho &= \rho^{-1}\delta_1 B_{n,2}^{(k,1)}\delta_1^{-1}\rho \\
&= \tau^{-1}\left(\sum_{i=0}^{r-1}\tau^{2i}R_n^{(k)}\tau^{-2i}\right)\tau \\
&= \tau\left(\sum_{i=0}^{r-1}\tau^{2i-2}R_n^{(k)}\tau^{2-2i}\right)\tau^{-1},
\end{aligned}$$

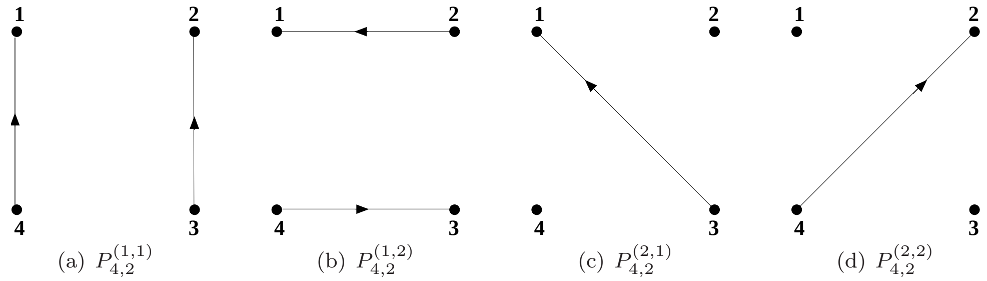
since $\rho^{-1}\delta_1 = \tau^{-1}$. Since $\tau^{-2} = -\tau^{2r-2}$, we have $\rho^{-1}B_{n,2}^{(k,1)}(2)\rho = \tau B_{n,1}^{(k,1)}\tau^{-1} = B_{n,2}^{(k,2)}$. A similar argument holds for $k = r$, noting that in this case, $\tau^{-2}R_n^{(k)} = \tau^{r-2}R_n^{(k)}$.

Figures 5 and 6 show the strictly period 2 primitives with 4 and 6 nodes.

As in the period 1 case, we obtain period 2 sink-type quivers by taking orbit-sums of the basis elements:

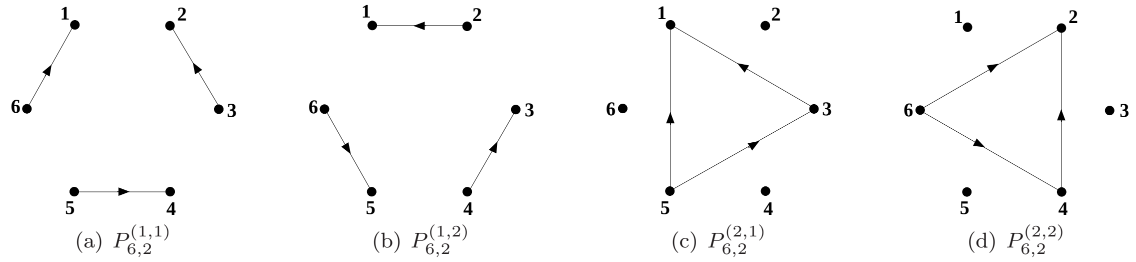
Proposition 4.3 (Classification of period 2 sink-type quivers) *If n is odd, there are no strictly period 2 sink-type quivers with n nodes. If $n = 2r$ is an even integer then every strictly period 2 sink-type quiver with n nodes has corresponding matrix of the form*

$$B = \begin{cases} \sum_{k=1}^{r}\sum_{j=1}^{2} m_{kj} B_{n,2}^{(k,j)} & \text{if } 4|n, \\ (\sum_{k=1}^{r-1}\sum_{j=1}^{2} m_{kj} B_{n,2}^{(k,j)}) + m_{r1} B_n^{(r)} & \text{if } 4\nmid n, \end{cases}$$



(a) $P_{4,2}^{(1,1)}$ (b) $P_{4,2}^{(1,2)}$ (c) $P_{4,2}^{(2,1)}$ (d) $P_{4,2}^{(2,2)}$

Figure 5: The strictly period 2 primitives for 4 nodes.



(a) $P_{6,2}^{(1,1)}$ (b) $P_{6,2}^{(1,2)}$ (c) $P_{6,2}^{(2,1)}$ (d) $P_{6,2}^{(2,2)}$

Figure 6: The period 2 primitives for 6 nodes

where the m_{jk} *are arbitrary nonnegative integers such that if* $4|n$, *there is at least one* k, $1 \leq k \leq r$, *such that* $m_{k1} \neq m_{k2}$, *and if* $4 \nmid n$, *there is at least one* k, $1 \leq k \leq r-1$, *such that* $m_{k1} \neq m_{k2}$.

Whilst the formulae above depend upon particular characteristics of the primitives, a similar relation exists for *any* period 2 quiver. For **any** quiver Q (regardless of any symmetry or periodicity properties), we have $\mu_{k+1}\,\rho\, Q = \rho\, \mu_k\, Q$, which just corresponds to relabelling the nodes. We write this symbolically as $\mu_{k+1}\rho = \rho\mu_k$ and $\rho^{-1}\mu_{k+1} = \mu_k\rho^{-1}$. For the period 2 case, the periodic chain (3) can be written

$$Q(1) \xrightarrow{\mu_1} Q(2) \xrightarrow{\mu_2} Q(3) = \rho^2 Q(1) \xrightarrow{\mu_3} Q(4) = \rho^2 Q(2) \xrightarrow{\mu_4} \cdots$$

Whilst μ_1 and μ_2 are genuinely different mutations, μ_3 and μ_4 are just μ_1 and μ_2 after relabelling. Since $\rho^{-1}\mu_2 Q(2) = \rho Q(1)$, we have $\mu_1(\rho^{-1}Q(2)) = \rho Q(1)$. We also have $\mu_2\,(\rho\, Q(1)) = \rho\, \mu_1\, Q(1) = \rho\, Q(2)$. We can extend the above diagram to that in Figure 7.

$$\begin{tikzcd}
\rho^{-1}\, Q(2) \arrow[r, "\mu_1"] & \rho\, Q(1) \arrow[r, "\mu_2"] & \rho\, Q(2) \arrow[r, "\mu_3"] & {} & \\
Q(1) \arrow[r, "\mu_1"'] & Q(2) \arrow[r, "\mu_2"'] \arrow[ul, "\rho^{-1}"'] & \rho^2\, Q(1) \arrow[r, "\mu_3"'] \arrow[ul, "\rho^{-1}"'] & \rho^2\, Q(2) \arrow[r, "\mu_4"'] \arrow[ul, "\rho^{-1}"'] & {}
\end{tikzcd}$$

Figure 7: Period 2 quivers and mutations

If $Q(1), Q(2)$ have *sinks* at nodes 1 and 2 respectively, then so do $\rho^{-1}Q(2)$ and $\rho Q(1)$ and the mutations μ_1 and μ_2 in the above diagram act *linearly.* This gives

$$\mu_1(Q(1) + \rho^{-1}Q(2)) = Q(2) + \rho\, Q(1) = \rho(Q(1) + \rho^{-1}Q(2))$$

and

$$\mu_2(Q(2) + \rho\, Q(1)) = \rho^2\, Q(1) + \rho\, Q(2) = \rho(Q(2) + \rho\, Q(1)),$$

so $Q(1) + \rho^{-1}Q(2)$ is period 1.

We have proved the following:

Proposition 4.4 *Let Q be period 2 sink-type quiver. Then $Q(1) + \rho^{-1}Q(2)$ is a quiver of period 1.*

5 Quivers with Higher Period

Higher period primitives are defined in a similar way. The periodic chain (3) contains m quivers $Q(1), Q(2), \ldots, Q(m)$, with corresponding matrices $B(1), \cdots, B(m)$.

Definition 5.1 (Period m sink-type quivers) *A quiver Q is said to be a* period m sink-type quiver *if it is of period m and, for $1 \le i \le m$, node i of $Q(i)$ is a sink.*

Thus the mutation $Q(i) \mapsto Q(i+1) = \mu_i Q(i)$ again only involves the reversal of arrows at node i, so can be achieved through a simple conjugation of its matrix: $\mu_i B(i) = \delta_i B(i) \delta_i$. Here

$$\delta_i = \mathrm{diag}(1, \cdots, 1, -1, 1, \cdots, 1) = \rho^{i-1}\delta_1\rho^{-i+1}$$

(with a "-1" in the ith position).

As in the period 1 and 2 cases, we obtain:

Lemma 5.2 (Period m sink-type equation) *Suppose that Q is a quiver with a sink at the ith node of $Q(i)$ for $i = 1, 2, \ldots, m$. Then Q is period m if and only if $\tau^m B_Q \tau^{-m} = B_Q$.*

Proof: We have that Q has period m if and only if $\delta_m \cdots \delta_1 B_Q \delta_1 \cdots \delta_m = \rho^m B_Q$, i.e. if and only if

$$B_Q = \delta_1 \cdots \delta_m \rho^m B_Q \rho^{-m} \delta_m \cdots \delta_1 = \tau^m B_Q \tau^{-m}.$$

□

Starting with the same matrices $R_n^{(k)}$, we now use the action $M \mapsto \tau^m M \tau^{-m}$ to build an invariant, i.e. we take orbit sums for τ^m. We only obtain strictly m-periodic elements in the case where the orbit has size divisible by m.

When $m|n$, the matrices $R_n^{(k)}$, for $1 \le k \le r-1$ (where $n = 2r$ or $2r+1$, r an integer), generate period m primitives $B_{n,m}^{(k,1)}$, with matrices given by

$$B_{n,m}^{(k,1)} = \sum_{i=0}^{(n/m)-1} \tau^{mi} R_n^{(k)} \tau^{-mi}.$$

Geometrically, the primitive $P_{n,m}^{(k,1)}$ is obtained from the primitive $P_n^{(k)}$ by only including every m^{th} arrow. As before, we form another $m-1$ period m primitives, $P_{n,m}^{(k,j)}$ for $j = 2, \ldots, n/m$, with matrices given by:

$$B_{n,m}^{(k,j)} = \tau^{j-1} B_{n,m}^{(k,1)} (\tau^{j-1})^{-1}.$$

Similarly, if $(2m)|n$ (so we are in the case $n = 2r$) then the τ^m-orbit-sum of $R_n^{(r)}$ is

$$B_{n,m}^{(k,1)} = \sum_{i=0}^{(n/2m)-1} \tau^{mi} R_n^{(r)} \tau^{-mi}.$$

with corresponding quiver $P_{n,m}^{(k,1)}$. We also obtain another $m-1$ period m primitives, $P_{n,m}^{(r,j)}$, for $j = 2, \ldots, m$, with matrices

$$B_{n,m}^{(r,j)} = \tau^{j-1} B_{n,m}^{(r,1)} (\tau^{j-1})^{-1}.$$

As in the period 1 and 2 cases, we obtain arbitrary strictly period m sink-type quivers by taking orbit-sums of the basis elements:

Proposition 5.3 (Classification of period m sink-type quivers) *If $m \nmid n$, there are no strictly period m sink-type quivers. If $(2m)|n$, the general strictly period m sink-type quiver is of the form*

$$B = \sum_{k=1}^{r} \sum_{j=1}^{m} m_{kj} B_{n,m}^{(k,j)},$$

where there is at least one k, $1 \le k \le r$, for which the m_{kj} are not all equal.

If $m|n$ but $(2m) \nmid n$ then the general period m sink-type quiver has the form

$$B = \begin{cases} \sum_{k=1}^{r} \sum_{j=1}^{m} m_{kj} B_{n,m}^{(k,j)} & \text{if } n = 2r+1 \text{ is odd;} \\ \sum_{k=1}^{r-1} \sum_{j=1}^{m} m_{kj} B_{n,m}^{(k,j)} + \sum_{j=1}^{m/2} m_{rj} B_{n,m/2)}^{(r,j)} & \text{if } n = 2r \text{ is even,} \end{cases}$$

where in the first case, there is at least one k, $1 \le k \le r$, for which the m_{kj} are not all equal, and in the second case, there is at least one k, $1 \le k \le r-1$, for which the m_{kj} are not all equal.

As before, we use $\mu_{k+1}\rho = \rho\mu_k$ and $\rho^{-1}\mu_{k+1} = \mu_k\rho^{-1}$, from which it follows that $\mu_k\rho^{-j} = \rho^{-j}\mu_{k+j}$. In turn, this gives

$$\mu_k \left(\rho^{-j}\, Q(j+k)\right) = \rho^{-j}\, \mu_{j+k}\, Q(j+k) = \rho^{-j}\, Q(j+k+1).$$

Suppose now that Q is a period m quiver. Then we have $Q(sm+j) = \rho^{sm}\, Q(j)$ for $1 \le j \le m$. We use this to extend the periodic chain (3) to an m level array. We have

$$\mu_1 \left(\rho^{-j}\, Q(j+1)\right) = \rho^{-j}\, Q(j+2), \;\; \mu_2 \left(\rho^{-j}\, Q(j+2)\right) = \rho^{-j}\, Q(j+3), \ldots,$$

arriving at

$$\mu_m \left(\rho^{-j}\, Q(j+m)\right) = \rho^{-j}\, Q(j+m+1) = \rho^m (\rho^{-j}\, Q(j+1)).$$

We write this period m sequence in the jth level of the array, i.e.

$$\rho^{-j}\, Q(j+1) \xrightarrow{\mu_1} \rho^{-j}\, Q(j+2) \xrightarrow{\mu_2} \cdots \xrightarrow{\mu_{m-1}} \rho^{-j}\, Q(j+m) \xrightarrow{\mu_m} \rho^m(\rho^{-j}\, Q(j+1)).$$

Again we have that if $Q(j)$ has a sink at node j for each j, then each $\rho^{-j}Q(j+1)$ has a sink at node 1 and the mutation μ_1 acts linearly. This gives

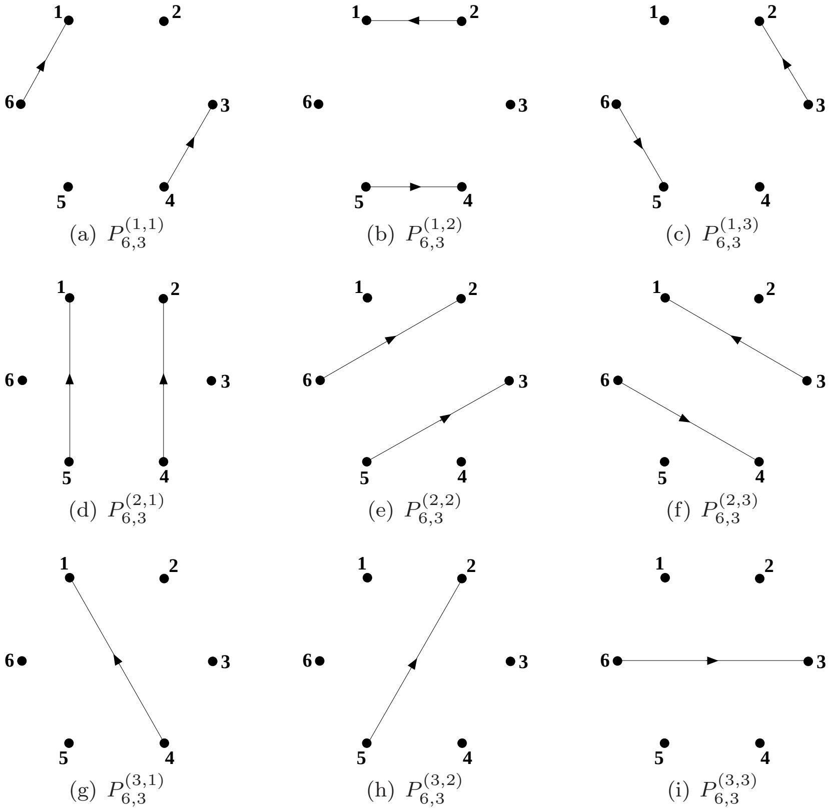
$$\mu_1(Q(1) + \rho^{-1}Q(2) + \cdots + \rho^{-m+1}Q(m)) = \rho(Q(1) + \rho^{-1}Q(2) + \cdots + \rho^{-m+1}Q(m)),$$

so $Q(1) + \rho^{-1}Q(2) + \cdots + \rho^{-m+1}Q(m)$ is period 1.

We have proved:

Proposition 5.4 *Let Q be period m sink-type quiver. Then $Q(1) + \rho^{-1}Q(2) + \cdots + \rho^{-m+1}Q(m)$ is a quiver of period 1.*

Example 5.5 (Period 3 Primitives) Proceeding as described above, whenever n is a multiple of 3 we obtain 3 period 3 primitives for each period 1 primitive. Figure 8 shows those with 6 nodes.



(a) $P_{6,3}^{(1,1)}$ (b) $P_{6,3}^{(1,2)}$ (c) $P_{6,3}^{(1,3)}$

(d) $P_{6,3}^{(2,1)}$ (e) $P_{6,3}^{(2,2)}$ (f) $P_{6,3}^{(2,3)}$

(g) $P_{6,3}^{(3,1)}$ (h) $P_{6,3}^{(3,2)}$ (i) $P_{6,3}^{(3,3)}$

Figure 8: The period 3 primitives for 6 nodes.

6 Period 1 General Solution

In this section we give an explicit construction of the $n \times n$ skew-symmetric matrices corresponding to arbitrary period 1 quivers, i.e. those for which mutation at node 1 has the same effect as the rotation ρ. We express the general solution as an explicit sum of period 1 primitives, thus giving a simple classification of all such quivers.

In anticipation of the final result, we consider the following matrix:

$$B = \begin{pmatrix} 0 & -m_1 & \cdots & -m_{n-1} \\ m_1 & 0 & & * \\ \vdots & & 0 & \\ m_{n-1} & * & & 0 \end{pmatrix}. \tag{5}$$

¿From (2), the general mutation rule at node 1 is

$$\tilde{b}_{ij} = \begin{cases} -b_{ij} & \text{if } i = 1 \text{ or } j = 1, \\ b_{ij} + \frac{1}{2}(|b_{i1}|b_{1j} + b_{i1}|b_{1j}|) & \textit{otherwise}. \end{cases} \tag{6}$$

The effect of the rotation $B \mapsto \rho B \rho^{-1}$ is to move the entries of B down and right one step, so that $(\rho B \rho^{-1})_{ij} = b_{i-1,j-1}$, remembering that indices are labelled modulo n, so $n + 1 \equiv 1$. For

$1 \le i, j \le n-1$, let

$$\delta_{ij} = \frac{1}{2}(m_i|m_j| - m_j|m_i|).$$

Then if m_i and m_j have the same sign, $\delta_{ij} = 0$. Otherwise $\delta_{ij} = \pm|m_i m_j|$, where the sign is that of m_i. Let $\widetilde{B} = \mu_1 B$, so that $\tilde{b}_{ij} = b_{ij} + \delta_{i-1,j-1}$.

Theorem 6.1 *Let B be an $n \times n$ skew-symmetric integer matrix. Let $b_{k1} = m_{k-1}$ for $k = 2, 3, \ldots, n$. Then $\mu_1 B = \rho B \rho^{-1}$ if and only if $m_r = m_{n-r}$ for $r = 1, 2, \ldots, n-1$, $b_{ij} = m_{i-j} + \delta_{1,i-j+1} + \delta_{2,i-j+2} + \cdots + \delta_{j-1,i-1}$ for all $i > j$, and B is symmetric along the non-leading diagonal.*

Proof: By skew-symmetry, we note that we only need to determine b_{ij} for $i > j$. We need to solve $\mu_1 B = \rho B \rho^{-1}$. By the above discussion, this is equivalent to solving

$$b_{ij} + \delta_{i-1,j-1} = b_{i-1,j-1}, \tag{7}$$

for $i > j$, with δ_{ij} as given above. Solving the equation leads to a recursive formula for b_{ij}.

We obtain

$$\begin{aligned}
b_{ij} &= b_{i-1,j-1} + \delta_{j-1,i-1} \\
&= b_{i-2,j-2} + \delta_{j-1,i-1} + \delta_{j-2,i-2} \\
&\;\vdots \\
&= b_{i-j+1,1} + \delta_{j-1,i-1} + \delta_{j-2,i-2} + \cdots + \delta_{1,i-j+1}.
\end{aligned}$$

In particular, we have:

$$b_{nj} = m_{n-j} + \delta_{1,n-j+1} + \delta_{2,n-j+2} + \cdots + \delta_{j-2,n-2} + \delta_{j-1,n-1}. \tag{8}$$

We also have that $m_j = \tilde{b}_{1,j+1} = (\rho B \rho^{-1})_{1,j+1} = b_{nj}$. In particular, $m_1 = b_{n1} = m_{n-1}$. Equation 8 gives

$$b_{n2} = m_{n-2} + \delta_{1,n-1} = m_{n-2} + \delta_{11} = m_{n-2}.$$

So $m_2 = m_{n-2}$. Suppose that we have shown that $m_j = m_{n-j}$ for $j = 1, 2, \ldots, r$. Then equation 8 gives

$$\begin{aligned}
b_{n,r+1} &= m_{n-r-1} + \delta_{1,n-r} + \delta_{2,n-r+1} + \cdots + \delta_{r,n-1} \\
&= m_{n-r-1} + \sum_{i=1}^{r} \delta_{i,n-r+i-1} \\
&= m_{n-r-1} + \sum_{i=1}^{r} \delta_{i,r+1-i} \\
&= m_{n-r-1} + \delta_{1,r} + \delta_{2,r-1} + \cdots + \delta_{r,1} = m_{n-r-1},
\end{aligned}$$

using the inductive hypothesis and the fact that $\delta_{st} = -\delta_{ts}$ for all s, t. Hence $m_{r+1} = m_{n-r-1}$ and we have by induction that $m_r = m_{n-r}$ for $1 \le r \le n-1$.

We have, for $i > j$, by equation (8),

$$\begin{aligned}
b_{n-j+1,n-i+1} &= m_{(n-j+1)-(n-i+1)} + \delta_{(n-i+1)-1,(n-j+1)-1} + \delta_{(n-i+1)-2,(n-j+1)-2} + \cdots + \delta_{1,(n-j+1)-(n-i+1)+1} \\
&= m_{i-j} + \delta_{n-i,n-j} + \delta_{n-i-1,n-j-1} + \cdots + \delta_{1,i-j+1},
\end{aligned}$$

and we have, again using (8) and the fact that $\delta_{n-a,n-b} = \delta_{ab}$,

$$\begin{aligned} m_{i-j} = m_{n-i+j} &= b_{n,n-i+j} \\ &= b_{n-j+1,n-i+1} + \delta_{n-i+j-1,n-1} + \delta_{n-i+j-2,n-2} + \cdots + \delta_{n-i+1,n-j+1} \\ &= b_{n-j+1,n-i+1} + \delta_{i-j+1,1} + \delta_{i-j+2,2} + \cdots + \delta_{i-1,j-1}, \end{aligned}$$

so

$$b_{n-j+1,n-i+1} = m_{i-j} + \delta_{j-1,i-1} + \cdots + \delta_{i-j+2,2} + \delta_{1,i-j+1} = b_{ij}.$$

Hence B is symmetric along the non-leading diagonal.

If B satisfies all the requirements in the statement of the theorem, then equation 8 is satisfied, and therefore $\rho B \rho^{-1} = \mu_1 B$. The proof is complete.□

We remark that with the identification $m_r = m_{n-r}$, we have seen that the formula (8) has a symmetry, due to which the δ's cancel in pairwise fashion:

$$b_{n,n-k+1} = b_{k1} + \delta_{1k} + \delta_{2,k+1} + \cdots + \delta_{k+1,2} + \delta_{k1}$$

The formula (8) is just a truncation of this, so not all terms cancel. As we march from b_{k1} in a "south easterly direction", we first add $\delta_{1k}, \delta_{2,k+1}$, etc, until we reach $\delta_{r,r+1}$ (when $n-k=2r$) or $\delta_{rr} = 0$ (when $n-k = 2r+1$). At this stage we start to subtract terms on a basis of "last in, first out", with the result that the matrix has reflective symmetry about the second diagonal as we have seen.

Remark 6.2 (Sink-type case) *We note that if all the m_i have the same sign, then all the δ_{ij} are zero. Equation (7) reduces to $b_{ij} = b_{i-1,j-1}$ and we recover the sink-type period 1 solutions considered in Proposition 3.6.*

6.1 Examples

The simplest nontrivial example is when $n = 4$.

Example 6.3 (Period 1 Quiver with 4 Nodes) Here the matrix has the form

$$B = \begin{pmatrix} 0 & -m_1 & -m_2 & -m_1 \\ m_1 & 0 & -m_1 - \delta_{12} & -m_2 \\ m_2 & m_1 + \delta_{12} & 0 & -m_1 \\ m_1 & m_2 & m_1 & 0 \end{pmatrix},$$

As previously noted, if m_1 and m_2 have the same sign, then $\delta_{12} = 0$ and this matrix is just the sum of primitives for 4 nodes. The 2×2 matrix in the "centre" of B (formed out of rows and columns 2 and 3),

$$\begin{pmatrix} 0 & -\delta_{12} \\ \delta_{12} & 0 \end{pmatrix},$$

corresponds to δ_{12} times the primitive $P_2^{(1)}$ with 2 nodes (see Figure 2). For the case $m_1 = 1, m_2 = -2, \delta_{12} = 2$, we obtain the Somos 4 quiver in Figure 1(a). The action of ι (see Remark 3.5) is $1 \leftrightarrow 4, 2 \leftrightarrow 3$ and clearly just reverses all the arrows as predicted by Remark 3.5.

Example 6.4 (Period 1 Quiver with 5 Nodes) Here the general period 1 solution has the form

$$B=\begin{pmatrix} 0 & -m_1 & -m_2 & -m_2 & -m_1 \\ m_1 & 0 & -m_1-\delta_{12} & -m_2-\delta_{12} & -m_2 \\ m_2 & m_1+\delta_{12} & 0 & -m_1-\delta_{12} & -m_2 \\ m_2 & m_2+\delta_{12} & m_1+\delta_{12} & 0 & -m_1 \\ m_1 & m_2 & m_2 & m_1 & 0 \end{pmatrix}$$

which can be written as

$$B=\sum_{k=1}^{2} m_k\, B_5^{(k)}+\delta_{12}B_3^{(1)},$$

where $B_3^{(1)}$ is embedded symmetrically in the middle of a 5×5 matrix (surrounded by zeros).

When $m_1=1$ and $m_2=-1$, this matrix corresponds to the Somos 5 sequence; see Figure 9 for the corresponding quiver.

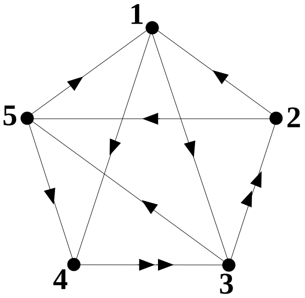


Figure 9: The Somos 5 quiver.

Example 6.5 (Period 1 Quiver with 6 Nodes) Here the matrix has the form

$$\begin{aligned} B \quad = \quad & \begin{pmatrix} 0 & -m_1 & -m_2 & -m_3 & -m_2 & -m_1 \\ m_1 & 0 & -m_1 & -m_2 & -m_3 & -m_2 \\ m_2 & m_1 & 0 & -m_1 & -m_2 & -m_3 \\ m_3 & m_2 & m_1 & 0 & -m_1 & -m_2 \\ m_2 & m_3 & m_2 & m_1 & 0 & -m_1 \\ m_1 & m_2 & m_3 & m_2 & m_1 & 0 \end{pmatrix} \\ & + \left(\begin{array}{c|cccc|c} 0 & 0 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & -\delta_{12} & -\delta_{13} & -\delta_{12} & 0 \\ 0 & \delta_{12} & 0 & -\delta_{12} & -\delta_{13} & 0 \\ 0 & \delta_{13} & \delta_{12} & 0 & -\delta_{12} & 0 \\ 0 & \delta_{12} & \delta_{13} & \delta_{12} & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right) + \left(\begin{array}{cc|cc|cc} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & -\delta_{23} & 0 & 0 \\ 0 & 0 & \delta_{23} & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right), \end{aligned}$$

which can be written as

$$B=\sum_{j=1}^{3} m_k\, B_6^{(k)}+\sum_{k=1}^{2}\delta_{1,k+1}\, B_4^{(k)}+\delta_{23}\, B_2^{(1)},$$

where the periodic solutions with fewer rows and columns are embedded symmetrically within a 6×6 matrix.

6.2 The Period 1 General Solution in Terms of Primitives

It can be seen from the above examples that the solutions are built out of a sequence of sub-matrices, each of which corresponds to one of the primitives. The main matrix is just an integer linear combination of primitive matrices for the full set of n nodes. The next matrix is a combination (with coefficients δ_{1j}) of primitive matrices for the $n-2$ nodes $2, \cdots, n-1$. We continue to reduce by 2 until we reach either 2 nodes (when n is even) or 3 nodes (when n is odd).

Remarkably, as can be seen from the general structure of the matrix given by (8), together with the symmetry $m_{n-r} = m_r$, this description holds for all n.

Recall that for an even (or odd) number of nodes, $n = 2r$ (or $n = 2r+1$), there are r *primitives*, labelled $B_{2r}^{(k)}$ (or $B_{2r+1}^{(k)}$), $k = 1, \cdots, r$. We denote the general linear combination of these by

$$\widetilde{B}_{2r}(\mu_1, \cdots, \mu_r) = \sum_{j=1}^{r} \mu_j B_{2r}^{(j)}, \quad \text{or} \quad \widetilde{B}_{2r+1}(\mu_1, \cdots, \mu_r) = \sum_{j=1}^{r} \mu_j B_{2r+1}^{(j)},$$

for integers μ_j.

The quivers corresponding to $\widetilde{B}_{2r}(\mu_1, \cdots, \mu_r)$ and $\widetilde{B}_{2r+1}(\mu_1, \cdots, \mu_r)$ (i.e. without the extra terms coming from the δ_{ij}) do not have periodicity properties (in general).

Theorem 6.6 (The general period 1 quiver) *Let B_{2r} (respectively B_{2r+1}) denote the matrix corresponding to the general even (respectively odd) node quiver of mutation periodicity 1. Then*

1.
$$B_{2r} = \widetilde{B}_{2r}(m_1, \cdots, m_r) + \sum_{k=1}^{r-1} \widetilde{B}_{2(r-k)}(\delta_{k,k+1}, \cdots, \delta_{kr}),$$
where the matrix $\widetilde{B}_{2(r-k)}(\delta_{k,k+1}, \cdots, \delta_{kr})$ is embedded in a $2r \times 2r$ matrix in rows and columns $k+1, \cdots, 2r-k$.

2.
$$B_{2r+1} = \widetilde{B}_{2r+1}(m_1, \cdots, m_r) + \sum_{k=1}^{r-1} \widetilde{B}_{2(r-k)+1}(\delta_{k,k+1}, \cdots, \delta_{kr}),$$
where the matrix $\widetilde{B}_{2(r-k)+1}(\delta_{k,k+1}, \cdots, \delta_{kr})$ is embedded in a $2r+1 \times 2r+1$ matrix in rows and columns $k+1, \cdots, 2r+1-k$.

7 Quivers with Mutation Periodicity 2

Already at period 2, we cannot give a full classification of the possible quivers. However, we can give the *full list* for low values of n, the number of nodes. We can also give a class of period 2 quivers which exists for odd or even n.

When n is *even*, primitives play a role, but the full solution cannot be written purely in terms of primitives. When n is *odd*, primitives do not even exist, but there are still quivers with mutation periodicity 2.

Consider the period 2 chain:

$$Q(1) \xrightarrow{\mu_1} Q(2) \xrightarrow{\mu_2} Q(3) = \rho^2 Q(1)$$

A simpler way to compute is to use $\mu_2 Q(3) = Q(2)$, so $\mu_2\rho^2 Q(1) = Q(2)$. Hence we must solve

$$\rho\mu_1\rho Q(1) = \mu_1 Q(1), \tag{9}$$

which are the equations referred to below. We first consider the solution of these equations for $n = 3, \cdots, 5$.

We need one new piece of notation, which generalises our former δ_{ij}. We define

$$\delta(x, y) = \frac{1}{2}\left(x|y| - y|x|\right).$$

Thus, $\delta_{ij} = \delta(m_i, m_j)$.

7.1 3 Node Quivers of Period 2

Here we omit the details, as they are easy to check.

$$B(1) = \begin{pmatrix} 0 & -2 & 2 \\ 2 & 0 & -2 \\ -2 & 2 & 0 \end{pmatrix}.$$

This corresponds to a $3-$cycle of double arrows. Notice that in this case, there are no free parameters. Mutating at node 1 just gives $B(2) = -B(1)$, i.e. $Q(2) = Q(1)^{opp}$. Note that the representation theoretic properties of this quiver are discussed at some length in [3, §8,§11].

7.2 4 Node Quivers of Period 2

Starting with the matrix

$$B(1) = \begin{pmatrix} 0 & -m_1 & -m_2 & -m_3 \\ m_1 & 0 & -b_{32} & b_{42} \\ m_2 & b_{32} & 0 & -b_{43} \\ m_3 & b_{42} & b_{43} & 0 \end{pmatrix},$$

we immediately find

$$b_{43} = m_1, \quad \text{and} \quad b_{32} = m_3 + \delta(m_1, p_1),$$

where we have written $b_{42} = p_1$, together with the 3 conditions:

$$\delta_{13} = 0, \quad \delta_{12} - \delta(m_1, p_1) = 0, \quad \delta_{23} + \delta(m_3, p_1) = 0.$$

The first of these just means that m_1 and m_3 have the same sign (or that one of them is zero). Choosing $m_1 > 0$, so $m_3 \geq 0$, we must have $m_2 < 0$ for node 1 *not* to be a sink. The remaining conditions are then

$$m_1(|p_1| - p_1 + 2m_2) = 0, \quad m_3(|p_1| - p_1 + 2m_2) = 0.$$

For a nontrivial solution we must have $p_1 < 0$, which leads to $p_1 = m_2$. The final result is then

$$\begin{aligned} B(1) &= \left(\begin{array}{cccc} 0 & -m_1 & -m_2 & -m_3 \\ m_1 & 0 & m_1m_2 - m_3 & -m_2 \\ m_2 & m_3 - m_1m_2 & 0 & -m_1 \\ m_3 & m_2 & m_1 & 0 \end{array}\right), \\ B(2) &= \left(\begin{array}{cccc} 0 & m_1 & m_2 & m_3 \\ -m_1 & 0 & -m_3 & -m_2 \\ -m_2 & m_3 & 0 & m_2m_3 - m_1 \\ -m_3 & m_2 & m_1 - m_2m_3 & 0 \end{array}\right). \end{aligned} \tag{10}$$

Notice that $B(2)(m_1, m_3) = \rho B(1)(m_3, m_1)\rho^{-1}$, so the period 2 property stems from the involution $m_1 \leftrightarrow m_3$. If $m_3 = m_1$, then the quiver has mutation period 1. We may choose either of these to be zero, but *not* m_2, since, again, node 1 would be a sink.

Remark 7.1 (The Quiver and its Opposite) *We made the choice that* $m_1 > 0$. *The equivalent choice* $m_1 < 0$ *would just lead to the negative of* $B(1)$*, corresponding to* $Q(1)^{opp}$.

Remark 7.2 (A Graph Symmetry) *Notice that the general quiver has the* **graph symmetry** $(1, 2, 3, 4) \leftrightarrow (4, 3, 2, 1)$*, under which* $Q \mapsto Q^{opp}$.

For $n \geq 5$*, we cannot construct the* general solution *of equations (9) without further assumptions. However, we can find* some *solutions and these also have this graph symmetry. Furthermore, if we* **assume** *the graph symmetry, then we* **can** *find the general solution for some higher values of* n*, but have no general proof that this will be the case for* **all** n.

We previously saw this graph symmetry in the context of period 1 *primitives (see Remark 3.5).*

7.3 5 Node Quivers of Period 2

Starting with the general skew-symmetric, 5×5 matrix, with

$$b_{k1} = m_{k-1}, \quad k = 2, \cdots, 5 \quad \text{and} \quad b_{52} = p_1,$$

we immediately find

$$b_{32} = m_4 + \delta_{12},\ b_{42} = m_2 + \delta_{14} + \delta(m_1, p_1),\ b_{43} = m_4 + \delta(m_1, p_1 - \delta_{14}),\ b_{53} = p_1 - \delta_{14},\ b_{54} = m_1,$$

together with the simple condition $m_3 = m_2 + \delta_{14}$ and four complicated conditions.

Imposing the graph symmetry (Remark 7.2) leads to $p_1 = m_2 = \delta_{14}$, after which two of the four conditions are identically satisfied, whilst the other pair reduce to a *single* condition:

$$\delta(m_2, p_1) + \delta(m_4, p_1) - \delta_{12} = m_4 - m_1.$$

We need integer solutions for m_1, m_2, m_4. There are a number of subcases

The case $m_1 > 0, m_4 > 0$

In this case the remaining condition reduces to

$$(|m_2| - m_2 - 2)(m_1 - m_4) = 0.$$

Discarding the period 1 solution, $m_4 = m_1$, we obtain $m_2 = -1$, leading to

$$\begin{aligned} B(1) &= \begin{pmatrix} 0 & -m_1 & 1 & 1 & -m_4 \\ m_1 & 0 & -m_1 - m_4 & 1 - m_1 & 1 \\ -1 & m_1 + m_4 & 0 & -m_1 - m_4 & 1 \\ -1 & m_1 - 1 & m_1 + m_4 & 0 & -m_1 \\ m_4 & -1 & -1 & m_1 & 0 \end{pmatrix}, \\ B(2) &= \begin{pmatrix} 0 & m_1 & -1 & -1 & m_4 \\ -m_1 & 0 & -m_4 & 1 & 1 \\ 1 & m_4 & 0 & -m_1 - m_4 & 1 - m_4 \\ 1 & -1 & m_1 + m_4 & 0 & -m_1 - m_4 \\ -m_4 & -1 & m_4 - 1 & m_1 + m_4 & 0 \end{pmatrix}. \end{aligned} \tag{11}$$

Notice again that $B(2)(m_1, m_4) = \rho B(1)(m_4, m_1)\rho^{-1}$, so the period 2 property stems from the involution $m_1 \leftrightarrow m_4$.

The case $m_1 > 0$, $m_4 < 0$, $m_2 > 0$

There is one condition, which can be reduced by noting that $m_2 - m_1 m_4 > 0$, giving

$$m_4(m_2 - 1) = m_1(m_4^2 - 1).$$

The left side is *negative* and the right *positive* unless $m_2 = 1$, $m_4 = -1$. We then have $m_3 = p_1 = m_1 + 1$, giving

$$\begin{aligned} B(1) &= \begin{pmatrix} 0 & -m_1 & -1 & -m_1 - 1 & 1 \\ m_1 & 0 & 1 & -m_1 - 1 & -m_1 - 1 \\ 1 & -1 & 0 & 1 & -1 \\ m_1 + 1 & m_1 + 1 & -1 & 0 & -m_1 \\ -1 & m_1 + 1 & 1 & m_1 & 0 \end{pmatrix}, \\ B(2) &= \begin{pmatrix} 0 & m_1 & 1 & m_1 + 1 & -1 \\ -m_1 & 0 & 1 & -m_1 - 1 & -1 \\ -1 & -1 & 0 & 1 & 0 \\ -m_1 - 1 & m_1 + 1 & -1 & 0 & 1 \\ 1 & 1 & 0 & -1 & 0 \end{pmatrix}. \end{aligned} \tag{12}$$

The case $m_1 > 0$, $m_4 < 0$, $m_2 < 0$

Here we have no control over the sign of $m_2 - m_1 m_4$.

When $m_2 - m_1 m_4 > 0$, we have the single condition

$$(m_2 - m_1 m_4)(m_2 + m_4) + m_1(m_2 + 1) - m_4 = 0.$$

Whilst any integer solution would give an example, we have no way of determining these.

When $m_2 - m_1 m_4 < 0$, we have $m_4 = m_1(m_2 + 1)$, so $m_3 = m_2 - m_1 m_4 = m_2 - m_1^2(m_2 + 1)$. We must have $m_2 \leq -2$ for $m_4 < 0$. Since $m_2 - m_1 m_4 = m_2 - m_1^2(m_2 + 1) < 0$, we then choose m_1 to be any integer satisfying $m_1 > \sqrt{\frac{m_2}{m_2+1}}$.

Subject to these constraints, the matrices take the form:

$$
\begin{aligned}
B(1) &= \begin{pmatrix} 0 & -m_1 & -m_2 & -m_3 & -m_1(m_2+1) \\ m_1 & 0 & -m_1 & m_3(m_1-1) & -m_3 \\ m_2 & m_1 & 0 & -m_1 & -m_2 \\ m_3 & -m_3(m_1-1) & m_1 & 0 & -m_1 \\ m_1(m_2+1) & m_3 & m_2 & m_1 & 0 \end{pmatrix}, \\
B(2) &= \begin{pmatrix} 0 & m_1 & m_2 & m_3 & m_1(m_2+1) \\ -m_1 & 0 & -m_1(m_2+1) & m_3 & -m_2 \\ -m_2 & m_1(m_2+1) & 0 & -m_1 & -m_2 \\ -m_3 & -m_3 & m_1 & 0 & -m_1 \\ -m_1(m_2+1) & m_2 & m_2 & m_1 & 0 \end{pmatrix}.
\end{aligned}
\tag{13}
$$

The simplest solution has $m_1 = 2$, $m_2 = -2$.

7.4 A Family of Period 2 Solutions

We are not able to classify all period 2 quivers. Note that in Section 4 we have classified all sink type period 2 quivers. In this section we shall explain how to modify the proof of the classification of period 1 quivers (see Section 6) in order to construct a family of period 2 quivers (which are, in general, not of sink type). The introduction of the involution σ, defined below, is motivated by the matrices (10) and (11).

As before, we consider the matrix:

$$
B = \begin{pmatrix} 0 & -m_1 & \cdots & -m_{n-1} \\ m_1 & 0 & & * \\ \vdots & & 0 & \\ m_{n-1} & * & & 0 \end{pmatrix}. \tag{14}
$$

However, we assume that, for $r = 2, 3, \ldots, n-2$, $m_r = m_{n-r}$ (in the period 1 case this property follows automatically). We also assume that $m_1 \geq 0$, $m_{n-1} = m_{\bar{1}} \geq 0$ and $m_1 \neq m_{\bar{1}}$ (the last condition to ensure we obtain strictly period 2 matrices). We consider the involution σ which takes m_r to m_r for $r \neq 1$ and interchanges m_1 and $m_{\bar{1}}$. Let $\mathbf{m} = (m_1, m_2, \ldots, m_{n-2}, m_{\bar{1}})$. We write $\sigma(\mathbf{m}) = \sigma(m_1, m_2, \ldots, m_{n-2}, m_{\bar{1}}) = (m_{\bar{1}}, m_2, \ldots, m_{n-2}, m_1)$.

Our aim is to construct a matrix $B = B(m_1, m_2, \ldots, m_{n-1})$ which satisfies the equation

$$
\mu_1(B) = \rho B(\sigma(\mathbf{m}))\rho^{-1}. \tag{15}
$$

Since σ is an involution, we shall obtain period 2 solutions in this way. As in the period 1 case, equation (15) implies that $(b_{n1}, b_{n2}, \ldots, b_{nn-1}) = \sigma(\mathbf{m})$. The derivation of (7) in the period 1 case is modified by the action of σ to give

$$
b_{ij} = \sigma(b_{i-1,j-1}) + \delta_{j-1,i-1}. \tag{16}
$$

An easy induction shows that:

$$
b_{ij} = \sigma^{j-1}(b_{i-j+1,1}) + \sum_{s=1}^{j-1} \sigma^{j-1-s}(\delta_{s,i-j+s}).
$$

Applying this in the case $i = n$ we obtain

$$b_{nj} = \sigma^{j-1}(b_{n-j+1,1}) + \sum_{s=1}^{j-1} \sigma^{j-1-s}(\delta_{s,n-j+s}).$$

Hence we have

$$b_{nj} = \sigma^{j-1}(b_{n-j+1,1}) + \delta_{j-1,\overline{1}} + \sum_{s=1}^{j-2} \sigma^{j-1-s}(\delta_{s,j-s}))$$

For $j \leq n-2$, this gives

$$m_j = m_{n-j} + \sigma^{j-2}(\delta_{1,j-1}) + \delta_{j-1,\overline{1}}.$$

Since $m_j = m_{n-j}$, this is equivalent to $\sigma^{j-2}(\delta_{1,j-1}) + \delta_{j-1,\overline{1}} = 0$. For $j = 2$ this is automatically satisfied, since $\delta_{1\overline{1}} = 0$. For $j \geq 3$ and odd, this is always true. For $j \geq 4$ and even, this is true if and only if $m_{j-1} \geq 0$. For $j = n-1$, we obtain

$$m_1 = b_{n,n-1} = \sigma^{n-2}(m_1) + \delta_{2,\overline{1}} + \sum_{s=1}^{n-3} \sigma^{n-2-s}(\delta_{s,j-s})$$

and thus

$$m_1 = \sigma^{n-2}(m_1) + \sigma^{n-3}(\delta_{1,2}) + \delta_{2,\overline{1}}.$$

For n even this is equivalent to $\delta_{\overline{1},2} + \delta_{2,\overline{1}} = 0$, which always holds. For n odd this gives the condition

$$m_1 = m_{\overline{1}} + \delta_{1,2} + \delta_{2,\overline{1}}.$$

If $m_2 \geq 0$, this is equivalent to $m_1 = m_{\overline{1}}$, a contradiction to our assumption. If $m_2 < 0$, this is equivalent to $m_1 = m_{\overline{1}} - m_1 m_2 + m_2 m_{\overline{1}}$, which holds if and only if $m_2 = -1$ (since we have assumed that $m_1 \neq m_{\overline{1}}$). Therefore, we obtain a period 2 solution provided $m_r \geq 0$ for r odd, $r \geq 3$ and, in addition, $m_2 = -1$ for n odd.

8 Maps with the Laurent Property

As previously said, our original motivation for this work was the well known connection between cluster algebras and sequences with the Laurent property, developed by Fomin and Zelevinsky in [6, 7]. We note that cluster algebras were initially introduced (in [6]) in order to study total positivity of matrices and the (dual of the) canonical basis of Kashiwara [17] and Lusztig [18] for a quantised enveloping algebra.

In this section we use the cluster algebras associated to periodic quivers to construct sequences with the Laurent property. These are likely to be a rich source of integrable maps. Indeed, it is well known (see [16]) that the Somos 4 recurrence can be viewed as an integrable map, having a degenerate Poisson bracket and first integral, which can be reduced to a 2 dimensional symplectic map with first integral. This 2 dimensional map is a special case of the QRT [21] family of integrable maps. The Somos 4 Poisson bracket is a special case of that introduced in [11] for all cluster algebra structures. For many of the maps derived by the construction given in this section, it is also possible to construct first integrals, often enough to prove complete integrability. We do not yet have a complete picture, so do not discuss this property in general. However, the maps associated with our primitives are simple enough to treat in general and can even be linearised. This is presented in Section 9.

A (skew-symmetric, coefficient-free) cluster algebra is an algebraic structure which can be associated with a quiver. (Recall that we only consider quivers with no 1 or 2-cycles). Given a quiver (with N nodes), we attach a variable at each node, labelled $(x_1, \cdots, x_N)$. When we mutate the quiver we change the associated matrix according to formula (2) and, *in addition*, we transform the cluster variables $(x_1, \cdots, x_N) \mapsto (x_1, \cdots, \tilde{x}_\ell, \cdots, x_N)$, where

$$x_\ell \tilde{x}_\ell = \prod_{b_{i\ell}>0} x_i^{b_{i\ell}} + \prod_{b_{i\ell}<0} x_i^{-b_{i\ell}}, \qquad \tilde{x}_i = x_i \text{ for } i \neq \ell. \tag{17}$$

If one of these products is empty (which occurs when all $b_{i\ell}$ have the same sign) then it is replaced by the number 1. This formula is called the (cluster) *exchange relation*. Notice that it just depends upon the ℓ^{th} column of the matrix. Since the matrix is skew-symmetric, the variable x_ℓ **does not** occur on the right side of (17).

After this process we have a new quiver $\tilde{Q}$, with a new matrix $\tilde{B}$. This new quiver has cluster variables $(\tilde{x}_1, \cdots, \tilde{x}_N)$. However, since the exchange relation (17) acts as the identity on all except one variable, we write these new cluster variables as $(x_1, \cdots, \tilde{x}_\ell, \cdots, x_N)$. We can now repeat this process and mutate $\tilde{Q}$ at node p and produce a third quiver $\tilde{\tilde{Q}}$, with cluster variables $(x_1, \cdots, \tilde{x}_\ell, \cdots, \tilde{x}_p, \cdots, x_N)$, with $\tilde{x}_p$ being given by an analogous formula (17).

Remark 8.1 (Involutive Property of the Exchange Relation) *Since the matrix mutation formula (2) just changes the signs of the entries in column n, a* **second** *mutation at this node would entail an* **identical** *right hand side of (17) (just interchanging the two products), leading to*

$$\tilde{x}_\ell \tilde{\tilde{x}}_\ell = x_\ell \tilde{x}_\ell \quad \Rightarrow \quad \tilde{\tilde{x}}_\ell = x_\ell.$$

Therefore, the exchange relation is an involution.

Remark 8.2 (Equivalence of a Quiver and its Opposite) *The mutation formula (17) for a quiver and its opposite are identical since this corresponds to just a change of sign of the matrix entries $b_{i\ell}$. This is a reason for considering these quivers as* **equivalent** *in our context.*

In this paper we have introduced the notion of *mutation periodicity* and followed the convention that we mutate first at node 1, then at node 2, etc. Mutation periodicity (period m) meant that after m steps we return to a quiver which is equivalent (up to a specific permutation) to the original quiver Q (see the diagram (3)). The significance of this is that the mutation at node $m+1$ produces an exchange relation which is **identical in form** (but with a different labelling) to the exchange relation at node 1. The next mutation produces an exchange relation which is **identical in form** (but with a different labelling) to the exchange relation at node 2. We thus obtain a periodic listing of formulae, which can be interpreted as an iteration, as can be seen in the examples below.

Remark 8.3 (Fixing notation) *In previous sections we have used n to denote the number of nodes in a quiver. In this and section 9 quivers will have N nodes, whilst n will denote the* **discrete variable** *in our recurrence formulae. The letter k will continue to be used for labelling the primitives, but is only needed in Section 9.*

8.1 Period 1 Case

We start with cluster variables $(x_1, \cdots, x_N)$, with x_i situated at node i. We then successively mutate at nodes $1, 2, 3, \ldots$ and define $x_{N+1} = \tilde{x}_1$, $x_{N+2} = \tilde{x}_2$, etc. The exchange relation (17) gives us a formula of the type

$$x_n x_{n+N} = F(x_{n+1}, \cdots, x_{n+N-1}), \tag{18}$$

with F being the sum of two monomials. This is interpreted as an N^{th} order map of the real line, with initial conditions $x_i = c_i$ for $i = 1, \cdots, N$. Whilst the right hand side of (18) is *polynomial*, the formula for x_{n+N} involves a division by x_n. For a general polynomial F, this would mean that x_n, for $n > 2N$, is a complicated **rational function** of $c_1, \cdots, c_N$. However, in our case, F is derived through the cluster exchange relation (17), so, by a theorem of [6], x_n is just a **Laurent polynomial** in $c_1, \cdots, c_N$, for all n. In particular, if we start with $c_i = 1, i = 1, \cdots N$, then x_n is an **integer** for all n.

Remark 8.4 (F not F_n) *For emphasis, we repeat that for a generic quiver we would need to write F_n, since the formula would be different for each mutation. It is the special property of period* 1 *quivers which enables the formula to be written as a recurrence.*

Example 8.5 (4 Node Case) Consider Example 6.3, with $m_1 = r, m_2 = -s$, both r and s positive. With $r = 1, s = 2$, the quiver is shown in Figure 1(a). We start with the matrix

$$B(1) = \begin{pmatrix} 0 & -r & s & -r \\ r & 0 & -r(1+s) & s \\ -s & r(1+s) & 0 & -r \\ r & -s & r & 0 \end{pmatrix}$$

and mutate at node 1, with $(x_1, x_2, x_3, x_4) \mapsto (x_5, x_2, x_3, x_4)$. Formula (17) gives

$$x_1 x_5 = x_2^r x_4^r + x_3^s, \tag{19}$$

whilst the mutation formula (2) gives

$$B(2) = \begin{pmatrix} 0 & r & -s & r \\ -r & 0 & -r & s \\ s & r & 0 & -r(1+s) \\ -r & -s & r(1+s) & 0 \end{pmatrix}.$$

Note that the second column of this matrix has the same entries (up to permutation) as the first column of $B(1)$. This is because $\mu_1 B(1) = \rho B(1) \rho^{-1}$. Therefore, when we mutate $Q(2)$ at node 2, with $(x_5, x_2, x_3, x_4) \mapsto (x_5, x_6, x_3, x_4)$, formula (17) gives

$$x_2 x_6 = x_3^r x_5^r + x_4^s, \tag{20}$$

which is of the same form as (19), but with indices shifted by 1. Formulae (19) and (20) give us the beginning of the recurrence (18), which now explicitly takes the form

$$x_n x_{n+4} = x_{n+1}^r x_{n+3}^r + x_{n+2}^s.$$

When $r = 1, s = 2$, this is exactly the Somos 4 sequence (1). When $r = s = 1$, we obtain the recurrence considered by Dana Scott (see [10] and [14]). This case was also considered by Hone (see Theorem 1 in [16]), who showed that it is *super-integrable* and linearisable.

Example 8.6 (5 Node Case) Consider Example 6.4, with $m_1 = r, m_2 = -s$, both r and s positive. We start with the matrix

$$B = \begin{pmatrix} 0 & -r & s & s & -r \\ r & 0 & -r(1+s) & -s(r-1) & s \\ -s & r(1+s) & 0 & -r(1+s) & s \\ -s & s(r-1) & r(1+s) & 0 & -r \\ r & -s & -s & r & 0 \end{pmatrix}$$

and mutate at node 1, with $(x_1, x_2, x_3, x_4, x_5) \mapsto (x_6, x_2, x_3, x_4, x_5)$. Formula (17) gives

$$x_1 x_6 = x_2^r x_5^r + x_3^s x_4^s.$$

Proceeding as before, the general term in the recurrence (18) takes the form

$$x_n x_{n+5} = x_{n+1}^r x_{n+4}^r + x_{n+2}^s x_{n+3}^s,$$

which reduces to Somos 5 when $r = s = 1$ (giving us the quiver of Figure 9).

Example 8.7 (6 Node Case) Consider Example 6.5. The first thing to note is that there are 3 parameters m_i, so we have rather more possibilities in our choice of signs. Having already obtained Somos 4 and Somos 5, one may be lured into thinking that Somos 6 will arise. However, Somos 6

$$x_n x_{n+6} = x_{n+1} x_{n+5} + x_{n+2} x_{n+4} + x_{n+3}^2$$

has 3 terms, so cannot directly arise through the cluster exchange relation (17), although we remark that it is shown in [7] that the terms in the Somos 6 and Somos 7 sequences are Laurent polynomials in their initial terms. However, various subcases of Somos 6 **do** arise in our construction. They are, in fact, special cases of the Gale-Robinson sequence of Example 8.8.

The case $m_1 = r, m_2 = -s, m_3 = 0$ with r, s positive. We can read off the map from the first column of the matrix of Example 6.5, which is $(0, r, -s, 0, -s, r)^T$, giving

$$x_n x_{n+6} = x_{n+1}^r x_{n+5}^r + x_{n+2}^s x_{n+4}^s,$$

which gives the first two terms of Somos 6 when $r = s = 1$.

The case $m_1 = r, m_2 = 0, m_3 = -s$ with r, s positive. The first column of the matrix is now $(0, r, 0, -s, 0, r)^T$, giving

$$x_n x_{n+6} = x_{n+1}^r x_{n+5}^r + x_{n+3}^s.$$

For a subcase of Somos 6 we choose $r = 1, s = 2$.

The case $m_1 = 0, m_2 = r, m_3 = -s$ with r, s positive. The first column of the matrix is now $(0, 0, r, -s, r, 0)^T$, giving

$$x_n x_{n+6} = x_{n+2}^r x_{n+4}^r + x_{n+3}^s,$$

again with $r = 1, s = 2$.

Example 8.8 (Gale-Robinson Sequence (N nodes)) The 2−term Gale-Robinson recurrence (see Equation (6) of [10]) is given by

$$x_n x_{n+N} = x_{n+N-r} x_{n+r} + x_{n+N-s} x_{n+s},$$

for $0 < r < s \le N/2$, and is one of the examples highlighted in [7]. We remark that this corresponds to the period 1 quiver with $m_r = 1$ and $m_s = -1$ (unless $N = 2s$, in which case we take $m_s = -2$); see Theorem 6.6.

8.2 Period 2 Case

We start with cluster variables $(z_1, \cdots, z_N)$, with z_i situated at node i. We then successively mutate at nodes $1, 2, 3, \dots$ and define $z_{N+1} = \tilde{z}_1$, $z_{N+2} = \tilde{z}_2$, etc. However, the exchange relation (17) now gives us an *alternating pair* of formulae of the type

$$z_{2n-1}z_{2n-1+N} = F_0(z_{2n}, \cdots, z_{2n+N-2}), \;\; z_{2n}z_{2n+N} = F_1(z_{2n+1}, \cdots, z_{2n+N-1}), \;\; n = 1, 2, \cdots . \tag{21}$$

with F_i being the sum of two monomials. It is natural, therefore, to relabel the cluster variables as $x_n = z_{2n-1}$, $y_n = z_{2n}$ and to interpret the map as acting on the $x - y$ plane. When $N = 2m$, the map is of order m. When $N = 2m - 1$, the map is again of order m, but the first exchange relation plays the role of a **boundary condition**. We need m points in the plane to act as initial conditions. When $N = 2m$, the values $z_1, \cdots, z_{2m}$ define these m points. When $N = 2m-1$, we need z_{2m} **in addition** to the **given** initial conditions $z_1, \cdots, z_{2m-1}$. Again, since our maps are derived through the cluster exchange relation (17), the formulae for (x_n, y_n) are Laurent polynomials of initial conditions. In the case of $N = 2m - 1$, this really does mean initial conditions $z_1, \cdots, z_{2m-1}$. The expression for $y_m = z_{2m}$ is already a polynomial, so it is important that it **does not** occur in the denominators of later terms.

Example 8.9 (4 Node Case) Consider the general period 2 quiver with 4 nodes, which has corresponding matrices (10), which we write with $m_1 = r, m_2 = -s, m_3 = t$, where r, s, t are positive:

$$\begin{aligned} B(1) &= \begin{pmatrix} 0 & -r & s & -t \\ r & 0 & -t-rs & s \\ -s & t+rs & 0 & -r \\ t & -s & r & 0 \end{pmatrix}, \\ B(2) &= \begin{pmatrix} 0 & r & -s & t \\ -r & 0 & -t & s \\ s & t & 0 & -r-st \\ -t & -s & r+st & 0 \end{pmatrix}. \end{aligned} \tag{22}$$

Mutating $Q(1)$ at node 1, with $(z_1, z_2, z_3, z_4) \mapsto (z_5, z_2, z_3, z_4)$, formula (17) gives

$$z_1 z_5 = z_2^r z_4^t + z_3^s, \tag{23}$$

whilst mutating $Q(2)$ at node 2, with $(z_5, z_2, z_3, z_4) \mapsto (z_5, z_6, z_3, z_4)$, formula (17) gives

$$z_2 z_6 = z_3^t z_5^r + z_4^s, \tag{24}$$

When $t \neq r$ these formulae are not related by a shift of index. However, since $B(3) = \mu_2 B(2) = \rho^2 B(1) \rho^{-2}$, mutating $Q(3)$ at node 3, with $(z_5, z_6, z_3, z_4) \mapsto (z_5, z_6, z_7, z_4)$, leads to

$$z_3 z_7 = z_4^r z_6^t + z_5^s, \tag{25}$$

which is just (23) with a shift of 2 on the indices. This pattern continues, giving

$$x_n x_{n+2} = y_n^r y_{n+1}^t + x_{n+1}^s, \quad y_n y_{n+2} = x_{n+1}^t x_{n+2}^r + y_{n+1}^s. \tag{26}$$

The appearance of x_{n+2} in the definition of y_{n+2} is not a problem, since it can be replaced by the expression given by the first equation.

As shown in Figure 7, we could equally start with the matrices

$$\bar{B}(1)=\rho^{-1}B(2)\rho,\quad \bar{B}(2)=\rho B(1)\rho^{-1}.$$

Since $\bar{B}(1)(r,s,t)=B(1)(t,s,r), \bar{B}(2)(r,s,t)=B(2)(t,s,r)$, we obtain a mapping

$$u_nu_{n+2}=v_n^tv_{n+1}^r+u_{n+1}^s,\quad v_nv_{n+2}=u_{n+1}^ru_{n+2}^t+v_{n+1}^s, \tag{27}$$

where we have labelled the nodes as $\zeta_1,\zeta_2,\cdots$ and then substituted $u_k=\zeta_{2k-1}, v_k=\zeta_{2k}$. With initial conditions $(z_1,z_2,z_3,z_4)=(1,1,1,1)$ and $(\zeta_1,\zeta_2,\zeta_3,\zeta_4)=(1,1,1,1)$, mappings (26) and (27) generate *different* sequences of integers. However, just making the change $\zeta_4=2$, reproduces the original z_n sequence. This corresponds to a shift in the labelling of the nodes, given by

$$u_n=y_n,\quad v_n=x_{n+1},\quad n=1,2,\cdots$$

Example 8.10 (5 Node Case) Consider the case with matrices (11), which we write with $m_1=r, m_4=t$, where r,t are positive. The same procedure leads to the map

$$y_nx_{n+3}=y_{n+2}^rx_{n+1}^t+x_{n+2}y_{n+1},\quad x_{n+1}y_{n+3}=y_{n+1}^rx_{n+3}^t+x_{n+2}y_{n+2},\quad n=1,2,\cdots \tag{28}$$

together with

$$x_1y_3=y_1^rx_3^t+x_2y_2,$$

and initial conditions $(x_1,y_1,x_2,y_2,x_3)=(c_1,c_2,c_3,c_4,c_5)$. The iteration (28) is a third order map of the plane and y_3 acts as the sixth initial condition.

As above, it is possible to construct a companion map, corresponding to the choice

$$\bar{B}(1)=\rho^{-1}B(2)\rho,\quad \bar{B}(2)=\rho B(1)\rho^{-1}.$$

9 Linearisable Maps From Primitives

This section is concerned with the maps derived from *period* 1 *primitives*. Similar results can be shown for higher periods, but we omit these here.

Our primitive quivers are inherently simpler than composite ones (as their name suggests!). The mutation process (at node 1) reduces to a simple matrix conjugation. The cluster exchange relation is still nonlinear, but turns out to be **linearisable**, as is shown in this section.

Consider the k^{th} (period 1) primitive $P_N^{(k)}$ with N nodes, such as those depicted in Figures 2 to 4. As before, we attach a variable at each node, labelled $(x_1,\cdots,x_N)$, with x_k situated at node k. We then successively mutate at nodes $1,2,3,\dots$ and define $x_{n+1}=\tilde{x}_1$, $x_{n+2}=\tilde{x}_2$, etc. The periodicity property allows us to think of the n^{th} mutation as occurring at node 1, so we place x_n at node 1, x_{n+1} at node 2, etc. For this primitive, the exchange relation (17) gives us the formula

$$x_nx_{n+N}=x_{n+k}x_{n+N-k}+1, \tag{29}$$

since one of the products in (17) is empty. This is the n^{th} iteration, which we label E_n. For $k=1$, this is a genuinely new sequence for each N. However, when N is not prime, we can have $N=Mk$, with the sequence decoupling into k copies of an M^{th} order iteration.

Specifically, if $N=Mk$, for some integer M, the quiver $P_N^{(k)}$ separates into M disconnected components (see Figures 2(d), 4(b) and 4(c)). The corresponding sequence decouples into k copies of the sequence associated with the primitive $P_M^{(1)}$, since (29) then gives

$$x_nx_{n+Mk}=x_{n+k}x_{n+(M-1)k}+1.$$

With $n = mk - t$, $y^t_m = x_{mk-t}$, $0 \le t \le k-1$, this gives k identical iteration formulae

$$y^t_m y^t_{m+M} = y^t_{m+1} y^t_{m+M-1} + 1. \tag{30}$$

Thus if, in (29), we use the initial conditions $x_i = 1$, $1 \le i \le N$, we obtain k copies of the integer sequence generated by (30).

9.1 First Integrals

Subtracting the two equations E_n and E_{n+k} leads to

$$\frac{x_n + x_{n+2k}}{x_{n+k}} = \frac{x_{n+N-k} + x_{n+N+k}}{x_{n+N}}.$$

With the definition

$$J_{n,k} = \frac{x_n + x_{n+2k}}{x_{n+k}}, \tag{31}$$

we therefore have

$$J_{n+N-k,k} = J_{n,k}, \tag{32}$$

giving us $N-k$ independent functions $\{J_{i,k} : 1 \le i \le N-k\}$ (or equivalently $\{J_{i,k} : n \le i \le n+N-k-1\}$).

Remark 9.1 (Decoupled case) *Again, when $N = Mk$, for some integer M, the sequence (29) decouples into k copies of (30) and the sequence $J_{n,k}$ (with periodicity $N-k$) splits into k copies of the corresponding sequence of J's for the primitive $P^{(1)}_M$, since*

$$n = mk - t, \;\; I^t_{m,1} = J_{mk-t,k}, \;\; 0 \le t \le k-1 \quad \Rightarrow \quad I^t_{m+M-1,1} = I^t_{m,1}.$$

Let α be any function of $N-k$ variables and define $\alpha^{(n)} = \alpha(J_{n,k}, \cdots, J_{n+N-k-1,k})$. Then, from the periodicity (32), $\alpha^{(n+N-k)} = \alpha^{(n)}$ (it can happen that the function will have periodicity $r \le N-k$). Then the function

$$K^{(n)}_\alpha = \sum_{i=0}^{N-k-1} \alpha^{(n+i)}$$

is a first integral for the map (29), meaning that it satisfies $K^{(n+1)}_\alpha = K^{(n)}_\alpha$. It is thus always possible to construct, for the map (29), $N-k$ independent first integrals. For $k=1$ this is the maximal number of integrals, unless the map is itself periodic (see [24] for the general theory of integrable maps).

For example, $N-k$ independent first integrals $\{K^{(n)}_p : 1 \le p \le N-k\}$ are given by

$$K^{(n)}_p = \sum_{i=0}^{N-k-1} \alpha^{(n+i)}_p, \quad \text{where} \quad \alpha^{(n)}_p = \prod_{i=0}^{p-1} J_{n+i,k}.$$

¿From the condition (32) and the definition (31), it can be seen that these depend upon the variables $x_n, \cdots, x_{n+N+k-1}$, so equation (29) must be used to eliminate $x_{n+N}, \cdots, x_{n+N+k-1}$ in order to get the correct form of these integrals in terms of the N independent coordinates.

Remark 9.2 (Decoupled case) *Again, when $N = Mk$,for some integer M, the sequence (29) decouples into k copies of (30) and we use the first integrals built out of the functions $I^t_{m,1}$.*

Let the sequence $\{x_n\}$ be given by the iteration (29), with initial conditions $\{x_i = a_i : 1 \leq i \leq N\}$. We have $K_p^{(n)} = K_p^{(1)}$, which is evaluated in terms of a_i. We also have $\{J_{i,k} = c_i : 1 \leq i \leq N-k\}$, together with the periodicity condition (32), which can also be written as $J_{n,k} = c_n$ with $c_{n+N-k} = c_n$. The first integrals $K_p^{(n)}$ have simpler formulae when written in terms of $c_1, \cdots, c_{N-k}$ (each of which is a rational function of the a_i).

9.2 A Linear Difference Equation

We show in this subsection that the difference equation (29) can be linearised.

Theorem 9.3 (Linearisation) *If the sequence $\{x_n\}$ is given by the iteration (29), with initial conditions $\{x_i = a_i : 1 \leq i \leq N\}$, then it also satisfies*

$$x_n + x_{n+2k(N-k)} = S_{N,k} x_{n+k(N-k)}, \tag{33}$$

where $S_{N,k}$ is a function of $c_1, \cdots, c_{N-k}$, which is symmetric under cyclic permutations.

Proof of case $k=1$: We first prove this theorem for the case $k=1$, later showing that the general case can be reduced to this.

We fix $k=1$. For $i \in \mathbb{N}$, let $L_i = x_i + x_{i+2} - c_i x_{i+1}$. For $1 \leq i \leq 2N-3$, we have that $J_{i,1} = c_i$ (see the last paragraph of the previous section), from which it follows that $L_i = 0$, but we regard the x_i as formal variables for the time being (see the end of the proof of Proposition 9.6). For $i = 0, 1, \dots, 2N-2$, we define a sequence a_i as follows. Set $a_0 = 0, a_1 = 1$ and then, for $2 \leq n \leq N-1$, define a_n recursively by:

$$a_n = -a_{n-2} - c_{n-1} a_{n-1}. \tag{34}$$

We also set $b_{2N-2} = 0$, $b_{2N-3} = 1$ and then, for $N-1 \leq n \leq 2N-3$, define b_n recursively by:

$$b_n = -b_{n+2} - c_{n+1} b_{n+1}. \tag{35}$$

Lemma 9.4 *For $0 \leq n \leq N-1$, we have $b_{2N-2-n} = a_n|_{c_l \mapsto c_{2N-2-l}}$.*

Proof: This is easily shown using induction on n and equations (34) and (35).□

The proofs of the following results (Lemma 9.5, Proposition 9.6 and Corollary 9.7) will be given in the Appendix. We first describe the a_n explicitly. Define:

$$t^n_{k,\text{odd}} = \sum_{\substack{1 \leq i_1 < i_2 < \cdots < i_k \leq n \\ i_1 \text{ odd}, i_2 \text{ even}, \dots}} c_{i_1} c_{i_2} \cdots c_{i_k}$$

$$t^n_{k,\text{even}} = \sum_{\substack{1 \leq i_1 < i_2 < \cdots < i_k \leq n \\ i_1 \text{ even}, i_2 \text{ odd}, \dots}} c_{i_1} c_{i_2} \cdots c_{i_k}$$

Lemma 9.5 *Suppose that $0 \leq n \leq N-1$. Then*
(a) If $n = 2r$ is even,

$$a_{2r} = (-1)^r \sum_{k=0}^{r-1} (-1)^k t^{(2r-1)}_{2k+1,odd}.$$

(b) If $n = 2r-1$ is odd,

$$a_{2r-1} = (-1)^{r-1} \sum_{k=0}^{r-1} (-1)^k t^{(2r-2)}_{2k,odd}.$$

(c) We have $a_n = a_n|_{c_l \mapsto c_{n-l}}$ and $a_{N-1} = b_{N-1}$.

For $n \in \mathbb{N}$ and $0 \leq k \leq n$, define:

$$t^n_{k,alt} = \begin{cases} \sum_{\substack{1 \leq i_1 < i_2 < \cdots < i_k \leq n \\ i_1, i_2, \ldots, i_k \text{ of alternating parity}}} c_{i_1} c_{i_2} \cdots c_{i_k} & \text{if } k > 0; \\ 2 & \text{if } k = 0. \end{cases}$$

Let $L = \sum_{i=1}^{N-1} (-1)^i a_i L_i + \sum_{i=N}^{2N-3} (-1)^i b_i L_i$. Since $a_1 = b_{2N-3} = 1$, the coefficients of x_1 and x_{2N-1} in L are both 1. By equations (34) and (35), the coefficient of x_i in L is zero for $i = 2, 3, \ldots, N-1, N+2, \ldots, 2N-2$. By Lemma 9.5(c), $a_{N-1} = b_{N-1}$, and it follows that the coefficient of x_{N+1} is also zero. The coefficient of x_N is

$$S_{N,1} = (-1)^{N-2}(a_{N-2} + c_{N-1} a_{N-1} + b_N).$$

Note that $b_N = a_{N-2}|_{c_l \mapsto c_{2N-2-l}}$ by Lemma 9.4, so $b_N = a_{N-2}|_{c_l \mapsto c_{N-1-l}}$, since $c_{n+N-1} = c_n$. This allows us to compute the coefficient of x_N explicitly to give:

Proposition 9.6 *We have*

$$x_1 + x_{2N-1} = S_{N,1} x_N,$$

where

$$S_{N,1} = \begin{cases} (-1)^{r-1} \sum_{k=0}^{r-1} (-1)^k t^{(2r-1)}_{2k+1,alt} & \textit{if } N = 2r \textit{ is even;} \\ (-1)^{r-1} \sum_{k=0}^{r-1} (-1)^k t^{(2r-2)}_{2k,alt} & \textit{if } N = 2r-1 \textit{ is odd.} \end{cases}$$

Corollary 9.7 *For all $n \in \mathbb{N}$,*

$$x_n + x_{n+2(N-1)} = S_{N,1} x_{n+N-1},$$

where $S_{N,1}$ is as above.

Example 9.8 *We calculate $S_{N,1}$ for some small values of N. We have:*

$$\begin{aligned}
S_{2,1} &= c_1; \\
S_{3,1} &= c_1 c_2 - 2; \\
S_{4,1} &= c_1 c_2 c_3 - c_1 - c_2 - c_3; \\
S_{5,1} &= c_1 c_2 c_3 c_4 - c_1 c_2 - c_2 c_3 - c_3 c_4 - c_4 c_1 + 2; \\
S_{6,1} &= c_1 c_2 c_3 c_4 c_5 - c_1 c_2 c_3 - c_2 c_3 c_4 - c_3 c_4 c_5 - c_4 c_5 c_1 - c_5 c_1 c_2 + c_1 + c_2 + c_3 + c_4 + c_5; \\
S_{7,1} &= c_1 c_2 c_3 c_4 c_5 c_6 - c_1 c_2 c_3 c_4 - c_2 c_3 c_4 c_5 - c_3 c_4 c_5 c_6 - c_4 c_5 c_6 c_1 - c_5 c_6 c_1 c_2 - c_6 c_1 c_2 c_3 \\
&\qquad + c_1 c_2 + c_1 c_4 + c_1 c_6 + c_3 c_4 + c_3 c_6 + c_5 c_6 + c_2 c_3 + c_2 c_5 + c_4 c_5 - 2.
\end{aligned}$$

We remark that $N = 7$ gives the first example where the terms of fixed degree in $S_{N,1}$ (in this case degree 2) do not form a single orbit under the cyclic permutation $(1\ 2\ \cdots\ N-1)$.

The case of $N = 4$ can be found in [16].

9.2.1 The case of general $k > 1$

When $k > 1$, the system of equations $J_{n,k} = c_n$ (with $c_{n+N-k} = c_n$) splits into k subsystems. Writing $n = mk - r$ for some $m \geq 1$ and $0 \leq r < k$ we define

$$z_m = x_{mk-r}, \quad \text{and} \quad I^{(r)}_{m,1} = \frac{z_m + z_{m+2}}{z_{m+1}}.$$

Writing $J_{n,k}$ (see (31)) in terms of z_m, we see that $J_{n,k} = I^{(r)}_{m,1}$. Define $M = N - k + 1$, so $c_{n+M-1} = c_n$. If $gcd(N, k) = 1$, then, for each r, $I^{(r)}_{m,1}$ cycle through **all** of $c_1, \ldots, c_{M-1}$ (in some order). For $r = k - 1$, label this sequence of c_i as $d_1, \ldots, d_{M-1}$. It is important to note that, for other values of r, the order is just a cyclic permutation of $d_1, \ldots, d_{M-1}$. We therefore have the conditions for Corollary 9.7, giving

$$z_m + z_{m+2(M-1)} = S_{M,1}(d_1, \ldots, d_{M-1}) z_{m+(M-1)}.$$

Writing this in terms of x_n gives (33) with $S_{N,k} = S_{M,1}(d_1, \ldots, d_{M-1})$, given by Proposition 9.6.

When $(N, k) \neq 1$, we should first use (30) to reduce to the relatively prime case and proceed as above.

Remark 9.9 *We need $2k(N - k)$ initial conditions in order to generate a sequence with (33), but are only supplied with $\{x_i = a_i : 1 \leq i \leq N\}$. If we use the iteration (29) to generate the remaining initial conditions for (33), then (29) and (33) will generate exactly the same sequence of numbers.*

9.3 Pell's Equation

For $k = 1$, the sequence (29) arising from the primitive B^1_n has entries which are closely related to Pell's equation, as indicated to us by examples in [22], e.g. sequences A001519 and A001075 for $N = 2, N = 3$ respectively. By Theorem 9.3, we have

$$x_n + x_{n+2(N-1)} = S_{N,1} x_{n+N-1}, \tag{36}$$

for $n \geq 1$. We have set $x_n = 1$ for $1 \leq n \leq N$, and it is easy to check that $x_n = n - N + 1$ for $N \leq n \leq 2N - 1$. It follows that $S_{N,1} = N + 1$. Subsequences of the form $y_m = x_{m(N-1)+c}$ for some constant c satisfy the recurrence $y_m + y_{m+2} = (N + 1)y_{m+1}$ which has associated quadratic equation $\lambda^2 - (N + 1)\lambda + 1 = 0$, with roots

$$\alpha_\pm = \frac{N + 1 \pm \sqrt{(N + 1)^2 - 4}}{2}. \tag{37}$$

Proposition 9.10
(a) Suppose that $N = 2r - 1$ is odd. For $m \in \mathbb{Z}$, $m \geq 0$, let $a_m = x_{(N-1)m+r}$. Choose $1 \leq t \leq N - 1$, and let $b_m = x_{(N-1)m+t+1} - x_{(N-1)m+t}$. Then the pairs (a_m, b_m) for $m > 0$ are the positive integer solutions of the Pell equation $a^2 - (r^2 - 1)b^2 = 1$.
(b) Suppose that $N = 2r$ is even. Choose t, t' such that $1 \leq t \leq r$ and $1 \leq t' \leq N - 1$. For $m \in \mathbb{Z}$, $m \geq 0$, let $a_m = x_{(N-1)m+t} + x_{(N-1)m+N+1-t}$ and let $b_m = x_{(N-1)m+t'+1} - x_{(N-1)m+t'}$. Then the pairs (a_m, b_m) for $m > 0$ are the positive integer solutions of the Pell equation $a^2 - ((2r+1)^2 - 4)b^2 = 4$.

Proof: The general solution of $y_m + y_{m+2} = (N + 1)y_{m+1}$ is

$$y_m = A_+ \alpha_+^{m-1} + A_- \alpha_-^{m-1}$$

for arbitrary constants $A_\pm$. The description above of the initial terms in the sequence (x_n) gives initial terms (for $m = 0$ and 1) for the subsequences a_m and b_m in each case, and it follows that, in the odd case,

$$a_m + b_m \sqrt{r^2 - 1} = (r + \sqrt{r^2 - 1})^m,$$

and, in the even case,

$$a_m + b_m\sqrt{(2r+1)^2-4} = 2^{1-m}(2r+1+\sqrt{(2r+1)^2-4})^m.$$

In the odd case, it is well-known that these are the positive integer solutions to $a^2-(r^2-1)b^2=1$, and in the even case, the description of the solutions is given in [15] (see also [26, Theorem 1]). (For the $N=2$ case, see for example [22], sequence A001519). $\square$

10 Parameters and Coefficients

We recalled the definition of a skew-symmetric coefficient-free cluster algebra in Section 8. The general definition [6] of a cluster algebra allows for coefficients in the exchange relations. We use the *ice quiver* approach of [9, 2.2] in which some of the cluster variables are specified to be frozen. The definition of the cluster algebra is the same, except that mutation at the frozen cluster variables is not allowed.

We consider an initial cluster consisting of N unfrozen cluster variables $x_1, x_2, \ldots, x_N$ and M frozen cluster variables $y_1, y_2, \ldots, y_M$. Thus, each seed contains a cluster with N unfrozen cluster variables together with the frozen variables $y_1, \ldots, y_M$, which never change. The quiver in the seed has N unfrozen vertices $1, 2, \ldots, N$ and M frozen vertices $N+1, \ldots, N+M$. The exchange matrix B will be taken to be the corresponding skew-symmetric matrix. The entries $b_{N+i,N+j}$, $1 \le i, j \le M$ do not play a role, so we take them to be zero (equivalently, there are no arrows between vertices $N+1, \ldots, N+M$ of the quiver).

Note that in the usual frozen variable set-up, columns $N+1\ldots, N+M$ of B are not included. This makes no difference, since the entries in these columns do not appear in the exchange relations. They are determined by the rest of B since B is skew-symmetric, and by the above assumption on zero entries. In order to ensure that these entries remain zero, we must modify the mutation μ_i slightly: $\widetilde{\mu_i}$ is the same as μ_i except that the entries $b_{N+i,N+j}$, $1 \le i, j \le M$, remain zero by definition. We find it convenient to include the extra columns in order to study the period 1 ice quiver case.

The exchange relation can then be written as follows, for $1 \le \ell \le n$:

$$x_\ell \tilde{x}_\ell = \prod_{\substack{1\le i\le M \\ b_{N+i,\ell}>0}} y_i^{b_{N+i,\ell}} \prod_{\substack{1\le i\le N \\ b_{i\ell}>0}} x_i^{b_{i\ell}} + \prod_{\substack{1\le i\le M \\ b_{N+i,\ell}<0}} y_i^{-b_{N+i,\ell}} \prod_{\substack{1\le i\le N \\ b_{i\ell}<0}} x_i^{-b_{i\ell}} \tag{38}$$

Thus, the coefficients appearing in the exchange relation change with each successive mutation, since they depend on the exchange matrix.

Let $\widetilde{\rho} = \begin{pmatrix} \rho & \mathbf{0} \\ \mathbf{0} & I_M \end{pmatrix}$, where $\mathbf{0}$ denotes zeros and I_M denotes the $M\times M$ identity matrix. Thus $\widetilde{\rho}$ represents the permutation sending $(1, 2, \ldots, N)$ to $(N, 1, 2, \ldots, N-1)$ and fixing $N+1, \ldots, N+M$. Consider a quiver Q (with $N+M$ vertices as above), satisfying

$$\widetilde{\mu_1} B_Q = \widetilde{\rho} B_Q \widetilde{\rho}^{-1} \tag{39}$$

Since the effect of conjugation by $\widetilde{\rho}$ on the first N elements of each of the rows $N+1, \ldots, N+M$ of the matrix B_Q is to cyclically shift them along one position to the right (with the entries in the opposite positions in the extra columns cyclically moving down one position), it is easy to see that, if we mutate such a quiver Q successively at vertices $1, 2, \ldots, N, 1, 2, \ldots$ etc. we obtain (as in Section 8) a recurrence:

$$x_n x_{n+N} = F(x_{n+1}, \ldots, x_{n+N-1}, y_1, y_2, \ldots, y_M)$$

where F is a sum of two monomials in the x_i with coefficients given by fixed monomials in the y_i. By the Laurent Phenomenon [6, 3.1], each cluster variable can be written as a Laurent polynomial in $x_1, x_2, \ldots, x_N$ with coefficients in $\mathbb{Z}[y_1, y_2, \ldots, y_M]$. Thus, the recurrence will be Laurent in this sense.

To solve equation (39), it is clear that the induced subquiver of Q on vertices $1, 2, \ldots, N$ must be a period 1 quiver in our usual sense. So we assume that the entries b_{ij} for $1 \le i, j \le N$ are as in the general solution given in Theorem 6.1. For $1 \le i \le M$, the $N+i, j$ entry of $\widetilde{\rho} B_Q \widetilde{\rho}^{-1}$ is $b_{N+i,j-1}$ (where $j-1$ is read as N if $j = 1$). Thus we must solve the equations $b_{N+i,N} = -b_{N+i,1}$ and $b_{N+i,j-1} = b_{N+i,j} + \frac{1}{2}(b_{N+i,1}|b_{1,j}| + |b_{N+i,1}|b_{1,j})$ for $i = 1, 2, \ldots, M$ and $j = 2, \ldots, N$, noting that columns $N+1, \ldots, N+M$ will give rise to the same equations. It is clear that the solution of these is independent of i, so, without loss of generality, we can assume that $M = 1$. For simplicity, we write $c_j = b_{N+1,j}$.

We thus must solve the equations $c_N = -c_1$ and $c_{j-1} - c_j = \delta(c_1, m_{j-1})$ for $j = 2, \ldots, N$. Adding these, we obtain the constraint that

$$2c_1 = \sum_{j=1}^{N-1} \delta(c_1, m_j). \tag{40}$$

The solutions are given by the values of c_1 satisfying this constraint (using the other equations to write down the values of the other c_i).

If $N = 2r+1$ is odd, the constraint can be rewritten

$$2c_1 = c_1(|m_1| + \cdots + |m_r|) - |c_1|(m_1 + \cdots + m_r),$$

using the fact that $m_j = m_{N-j}$ for all j. For non-zero solutions, we must have $c_1 \neq 0$. For solutions with $c_1 > 0$, we must have

$$|m_1| - m_1 + |m_2| - m_2 + \cdots + |m_r| - m_r = 2.$$

Since $|x| - x = 0$ for $x \ge 0$ and equals $-2x$ for $x \le 0$, the only solutions arise when $m_t = -1$ for some t and all other m_j are nonnegative. They are of the form

$$c_j = \begin{cases} c_1, & 1 \le j \le t \\ 0, & t+1 \le j \le 2r+1-t \\ -c_1, & 2r+2-t \le j \le 2r+1. \end{cases}$$

The solutions with negative c_1 are the negative of these (provided $m_t = 1$ and all other m_j are nonpositive).

If $N = 2r$ is even, the constraint can be rewritten

$$2c_1 = c_1(|m_1| + \cdots + |m_{r-1}| + |m_r|/2) - |c_1|(m_1 + \cdots + m_{r-1} + m_r/2),$$

again using the fact that $m_j = m_{N-j}$ for all j. Thus for non-zero solutions with $c_1 > 0$, we must have

$$|m_1| - m_1 + |m_2| - m_2 + \cdots + |m_{r-1}| - m_{r-1} + |m_r|/2 - m_r/2 = 2.$$

Arguing as in the odd case, we see that solutions arise when $m_t = -1$ for some t with $1 \le t \le r-1$ and all other m_j are nonnegative, or when $m_r = -2$ and all other m_j are nonnegative. They are of the form

$$c_j = \begin{cases} c_1, & 1 \le j \le t \\ 0, & t+1 \le j \le 2r-t \\ -c_1, & 2r+1-t \le j \le 2r, \end{cases}$$

where $t = r$ for the last case. The solutions for negative c_1 are the negative of these (with the negative of the constraints on the m_j).

Example 10.1 (Somos 4 Recurrence with Parameters) We saw in Example 6.3 of Section 6.1 that the Somos 4 quiver corresponds to the case where $m_1 = 1$ and $m_2 = -2$. From the above we can see that we obtain solutions with both positive and negative c_1 (indeed, the Somos 4 quiver is the unique 4-node quiver with this property). Taking $c_1 = 1$ for the first extra row, $(1, 1, -1, -1)$ and $c_1 = -1$ for a second extra row, $(-1, 0, 0, 1)$, we get the quiver shown in Figure 10, with empty circles denoting frozen vertices. We recover the Laurent property of the corresponding recurrence:

$$x_{n+4}x_n = y_1x_{n+1}x_{n+3} + y_2x_{n+2}^2.$$

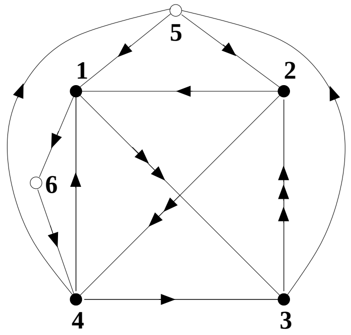

Figure 10: The ice quiver for Somos 4 with parameters.

Example 10.2 (A Recurrence Considered by Dana Scott) We have seen (see Example 8.5 of Section 8.1) that the case $m_1 = 1$, $m_2 = -1$ corresponds to a recurrence considered by Dana Scott. The above tells us that the only solutions to the constraint (40) for this case have $c_1 \leq 0$, corresponding to the recurrence

$$x_{n+4}x_n = x_{n+1}x_{n+3} + yx_{n+2}.$$

It follows that this recurrence is Laurent. The corollary, that this recurrence gives integers for all integer y (if $x_1 = x_2 = x_3 = x_4 = 1$), was noted in [10]. It is also noted in [10] that the recurrence

$$x_{n+4}x_n = 2x_{n+1}x_{n+3} + x_{n+2}$$

(with the same initial conditions) does not give integers. It follows that the recurrence

$$x_{n+4}x_n = y_1x_{n+1}x_{n+3} + y_2x_{n+2}$$

does not have the Laurent property.

Remark 10.3 (Two-term Gale-Robinson Sequence with Parameters) *We remark that the period* 1 *quivers that have both positive and negative solutions to the constraint equation (40) correspond precisely to the two-term Gale-Robinson sequences (see Example 8.8 of Section 8.1). Thus these sequences, with a parameter multiplying each of the terms, are Laurent. This was first shown in [7, 1.7].*

Remark 10.4 (A Conjecture) *Although our results do not determine non-Laurentness it is interesting to note that we obtain exactly those which are Laurent as solutions in the above examples. It seems reasonable to conjecture that the parameter versions of recurrences arising from period* 1 *quivers are Laurent if and only if they arise from a cluster algebra with frozen variables in the above sense.*

11 Supersymmetric Quiver Gauge Theories

In this section we point to the $D-$*brane* literature in which our quivers arise in the context of *quiver gauge theories*. The quivers arising in supersymmetric quiver gauge theories often have periodicity properties. Indeed, in [19, §3] the authors consider an $\mathcal{N} = 1$ supersymmetric quiver gauge theory associated to the complex cone over the second del Pezzo surface dP_2. The quiver Q_{dP_2} of the gauge theory they consider is given in Figure 11(d). The authors compute the Seiberg dual of the quiver gauge theory at each of the nodes of the quiver. The Seiberg dual theory has a new quiver, obtained using a combinatorial rule from the original quiver using the choice of vertex (see [5]). It can be checked that the combinatorial rule for Seiberg-dualising a quiver coincides with the rule for Fomin-Zelevinsky quiver mutation (Definition 2.1); see [25] for a discussion of the relationship between Seiberg duality and quiver mutation. In [19, §3] the authors compute the Seiberg dual of Q_{dP_2} at each node, in particular showing that the Seiberg dual of Q_{dP_2} at node 1 is an isomorphic quiver. They indicate that such behaviour is to be expected from a physical perspective.

This quiver fits into the scheme discussed in this article: it is a period 1 quiver. In fact it coincides with the quiver corresponding to the matrix $B_5^{(1)} - B_5^{(2)} + B_3^{(1)}$ (see Example 6.4 with $m_1 = 1, m_2 = -1$, and also Figure 9), with the relabelling $(1, 2, 3, 4, 5) \mapsto (3, 4, 5, 2, 1)$ (we give all relabellings starting from our labels). We note that this quiver also appears in [20] (with a relabelling $(1, 2, 3, 4, 5) \mapsto (2', 3', 1, 2, 3)$) in the context of a dP_2 brane tiling and that the corresponding sequence is the Somos 5 sequence.

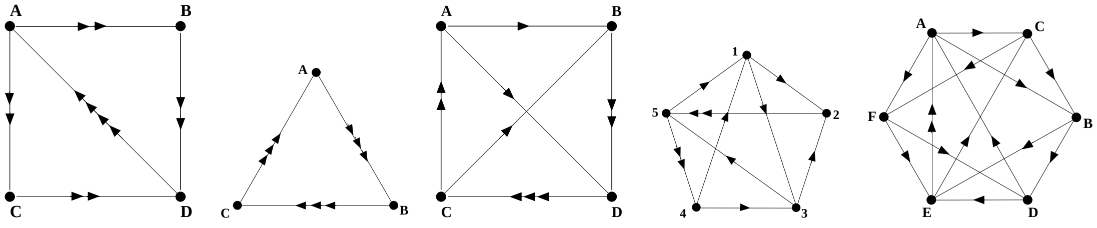
The quivers of quiver gauge theories associated to the complex cones over the Hirzebruch zero and del Pezzo 0–3 surfaces are computed in [4, §4]. We list them for convenience in Figure 11 for the Hirzebruch 0 and del Pezzo $0, 1$ and 3 surfaces. Note that the del Pezzo 2 case was discussed above: we chose the quiver given in [19, §3] for this case because it fits better into our setup. We remark that the quiver for dP_1 coincides with the Somos 4 quiver (with matrix $B_4^{(1)} - 2B_4^{(2)} + 2B_2^{(1)}$), with the relabelling $(1, 2, 3, 4) \mapsto (B, C, D, A)$. Thus it is period 1. See Example 6.3 and Figure 1(a).

The quiver for the Hirzebruch 0 surface is period 2: with the relabelling $(1, 2, 3, 4) \mapsto (C, A, D, B)$. It corresponds to the matrix $B(1)$ given in equation (10) in Section 7.2 with $m_1 = 2$, $m_2 = -2$ and $m_3 = 0$. The quiver for dP_3 is period two. In fact it is one of the period two quivers described in Section 7.4, with $m_1 = m_3 = 1$, $m_2 = -1$ and $m_{\overline{1}} = 0$.

Finally, we note that, by construction, the in-degree of a vertex i always coincides with the out-degree of i for any quiver arising from a brane tiling in the sense of [8]. It is interesting to note that the only quivers of cluster mutation period 1 satisfying this assumption with five or fewer vertices are the Somos 4 and Somos 5 quivers, i.e. quivers associated to dP_1 and dP_2 (see Figures 11(c) and 11(d)).

12 Conclusions

In this paper we have raised the problem of classifying all quivers with mutation periodicity. For period 1 we have given a *complete* solution. For period 2 we have given a solution which exists *for*



(a) Hirzebruch 0 (b) del Pezzo 0 (c) del Pezzo 1 (d) del Pezzo 2 (e) del Pezzo 3

Figure 11: Quivers of quiver gauge theories associated to a family of surfaces. Quiver (d) is from [19] while the others are from [4].

all N (the number of nodes). In addition to these, we have seen that, for $N = 5$ there are some "exceptional solutions", such as (12) and (13). We conjecture that such "exceptional solutions" will exist for all *odd* N, but not for the even case. We also conjecture that there are more general infinite families than the one presented in Section 7.4, where we took a particularly simple initial condition for the iteration (16). We could, for instance, consider the case with $m_{N-r} = m_{\overline{r}}$ for several values of r. We could also consider a family of *period* r quivers, satisfying $\mu_1(B) = \rho B(\sigma(\mathbf{m}))\rho^{-1}$, with $\sigma^r(\mathbf{m}) = \mathbf{m}$.

The other main theme of our paper was the construction and analysis of maps with the Laurent property. We have shown that the maps associated with our period 1 primitives can be linearised. This construction can be extended to higher period cases, but we currently only have examples. General periodic quivers give rise to truly nonlinear maps, the simplest of which is Somos 4, which is known [16] to be integrable and, in fact, related to the QRT [21] map of the plane. Somos 5 is similarly known to be integrable, as are the subcases of Somos 6 discussed in Example 8.7. On the other hand,

$$x_n x_{n+6} = x_{n+1}^2 x_{n+5}^2 + x_{n+2}^2 x_{n+3}^4 x_{n+4}^2,$$

(corresponding to the choice $m_1 = -m_2 = 2, m_3 = -4$ in Example 8.7) is known to be *not* integrable (see Equation (4.3) of [16]). Even though this iteration has the Laurent property and satisfies "singularity confinement" [12] (a type of Painlevé property for discrete equations), it fails the more stringent "algebraic entropy" [2] test for integrability. This simple test (or the related "diophantine integrability" [13] test) can very quickly show that a map is *not* integrable. If they *indicate* integrability, then it is sensible to search for *invariant functions* in order to *prove* integrability. Early indications (preliminary calculations by C-M Viallet) are that for integers m_i which are "small in absolute value" we have integrable cases. We thus expect that small sub-families of our general periodic quivers will give rise to integrable maps. A general investigation of this question would be very interesting.

We have seen that many of our examples occur in the context of supersymmetric quiver gauge theories. A deep understanding of the connection with brane tilings and related topics would be very interesting.

After this paper first appeared in the arXiv, Jan Stienstra pointed out to us that the quivers in Figure 11 also appear in [23] in the context of Gelfand-Kapranov-Zelevinsky hypergeometric systems in two variables, suggesting a possible connection between cluster mutation and such systems.

Acknowledgements

We would like to thank Jeanne Scott for some helpful discussions and Claude Viallet for computing the algebraic entropy of some of our maps. This work was supported by the Engineering and Physical Sciences Research Council [grant numbers EP/C01040X/2 and EP/G007497/1].

13 Appendix A1: Proofs of Results in Section 9.2

Proof of Lemma 9.5: We first prove (a) and (b). The result is clearly true for $n = 0, 1$. Assume that it holds for smaller n and firstly assume that $n = 2r - 1$ is odd. Then

$$\begin{aligned}
a_{2r-1} &= -a_{2r-3} - c_{2r-2}a_{2r-2} \\
&= (-1)^{r-1}\sum_{k=0}^{r-2}(-1)^k t_{2k,\mathrm{odd}}^{(2r-4)} + c_{2r-2}(-1)^r\sum_{k=0}^{r-2}(-1)^k t_{2k+1,\mathrm{odd}}^{(2r-3)} \\
&= (-1)^{r-1}t_{0,\mathrm{odd}}^{(2r-4)} + (-1)^{r-1}\sum_{k=0}^{r-3}(-1)^{k+1}t_{2k+2,\mathrm{odd}}^{(2r-4)} + c_{2r-2}(-1)^r\sum_{k=0}^{r-2}(-1)^k t_{2k+1,\mathrm{odd}}^{(2r-3)} \\
&= (-1)^{r-1}t_{0,\mathrm{odd}}^{(2r-4)} + (-1)^{2r-2}c_{2r-2}t_{2r-3,\mathrm{odd}}^{(2r-3)} + (-1)^r\sum_{k=0}^{r-3}(-1)^k(t_{2k+2,\mathrm{odd}}^{(2r-4)} + c_{2r-2}t_{2k+1,\mathrm{odd}}^{(2r-3)}) \\
&= (-1)^{r-1}t_{0,\mathrm{odd}}^{(2r-4)} + (-1)^{2r-2}t_{2r-2,\mathrm{odd}}^{(2r-2)} + (-1)^r\sum_{k=0}^{r-3}(-1)^k t_{2k+2,\mathrm{odd}}^{(2r-2)} \\
&= (-1)^{r-1}\sum_{k=0}^{r-1}(-1)^k t_{2k,\mathrm{odd}}^{(2r-2)},
\end{aligned}$$

and the result holds for n. A similar argument shows that the result holds for n when n is even. Then (a) and (b) follow by induction. To prove (c), we note that $t_{2k+1,\mathrm{odd}}^{(2r-1)}$ is invariant under the transformation $c_l \mapsto c_{2r-l}$ and that $t_{2k,\mathrm{odd}}^{(2r-2)}$ is invariant under $c_l \mapsto c_{2r-1-l}$. We then have

$$b_{N-1} = a_{N-1}|_{c_l\mapsto c_{2N-2-l}} = a_{N-1}|_{c_l\mapsto c_{N-1-l}} = a_{N-1}$$

using Lemma 9.4 and the fact that $c_{n+N-1} = c_n$.□

Proof of Proposition 9.6: We first assume that $N = 2r - 1$ is odd, so $(-1)^{N-2} = -1$. Then

$$\begin{aligned}
S_{N,1} &= -(a_{2r-3} + a_{2r-3}|_{c_l\mapsto 2r-2-l} + c_{2r-2}a_{2r-2}) \\
&= (-1)^{r-1}\sum_{k=0}^{r-2}(-1)^k t_{2k,\mathrm{odd}}^{(2r-4)} + (-1)^{r-1}\sum_{k=0}^{r-2}(-1)^k t_{2k,\mathrm{even}}^{(2r-3)} + c_{2r-2}(-1)^r\sum_{k=0}^{r-2}(-1)^k t_{2k+1,\mathrm{odd}}^{(2r-3)} \\
&= (-1)^{r-1}t_{0,\mathrm{odd}}^{(2r-4)} + (-1)^{r-1}\sum_{k=0}^{r-3}(-1)^{k+1}t_{2k+2,\mathrm{odd}}^{(2r-4)} + (-1)^{r-1}\sum_{k=0}^{r-2}(-1)^k t_{2k,\mathrm{even}}^{(2r-3)} \\
&\qquad + c_{2r-2}(-1)^r\sum_{k=0}^{r-2}(-1)^k t_{2k+1,\mathrm{odd}}^{(2r-3)} \\
&= (-1)^{r-1}t_{0,\mathrm{odd}}^{(2r-4)} + c_{2r-2}(-1)^{2r-2}t_{2r-3,\mathrm{odd}}^{(2r-3)} + (-1)^r\sum_{k=0}^{r-3}(-1)^k(t_{2k+2,\mathrm{odd}}^{(2r-4)} + c_{2r-2}t_{2k+1,\mathrm{odd}}^{(2r-3)})
\end{aligned}$$

$$
\begin{aligned}
&+(-1)^{r-1}\sum_{k=0}^{r-2}(-1)^k t_{2k,\mathrm{even}}^{(2r-3)} \\
&=(-1)^{r-1}t_{0,\mathrm{odd}}^{(2r-2)}+(-1)^{2r-2}t_{2r-2,\mathrm{odd}}^{(2r-2)}+(-1)^r\sum_{k=0}^{r-3}(-1)^k t_{2k+2,\mathrm{odd}}^{(2r-2)}+(-1)^{r-1}\sum_{k=0}^{r-2}(-1)^k t_{2k,\mathrm{even}}^{(2r-3)} \\
&=(-1)^{r-1}\sum_{k=0}^{r-1}(-1)^k t_{2k,\mathrm{odd}}^{(2r-2)}+(-1)^{r-1}\sum_{k=0}^{r-2}(-1)^k t_{2k,\mathrm{even}}^{(2r-2)} \\
&=(-1)^{r-1}\sum_{k=0}^{r-1}(-1)^k t_{2k,\mathrm{alt}}^{(2r-2)},
\end{aligned}
$$

as required. A similar argument shows that the result holds when N is even.

As we have already observed, for the sequence (x_i) we are interested in, the L_i vanish. It follows that L vanishes and we are done.□

Proof of Corollary 9.7: The proof of Proposition 9.6 also shows that $x_2+x_{2+2N-1} = S_{N,1}|_{c_l\mapsto c_{l+1}}x_{2+N-1}$. It follows from the description of $S_{N,1}$ in Proposition 9.6 that $S_{N,1} = S_{N,1}|_{c_l\mapsto c_{l+1}}$ (using the fact that $c_{n+N-1} = c_n$) so we are done for $n = 2$. Repeated application of this argument gives the result for arbitrary n.□
